Calamities and setbacks are a part of life. Twenty-four hour news coverage, with screaming headlines of disasters and mishaps around the world — earthquakes, mass shootings, severe storms, epidemics, data breaches or terrorist attacks — has become increasingly less shocking to our desensitized senses. Oftentimes, we are tempted to change the channel or turn down the volume or scroll past the headline.

However, as business and process owners, team leaders and business continuity practitioners, we do and must pay attention. We worry daily about all things impacting business continuity — the newly formed hurricane and how it may impact next week’s shipments, the cloud outage that disrupted e-commerce overnight, new regulations that may create additional operating bottlenecks, or the market’s possible reaction to missing a reporting deadline. Business continuity means contemplating all scenarios and solutions, regardless of the event’s cause and whether it was within our control.

In the current environment, in which businesses of all sizes and types are being tested in unprecedented ways by the coronavirus (COVID-19) pandemic, business continuity and resilience has become a critical discussion in boardrooms and C-suites around the world. The pandemic’s widespread impact has forced organizations to revisit business continuity planning (BCP) and how to embed BCP practices in day-to-day operations. Operational resilience has taken on new urgency, as the expectations of business leaders to lead resilience efforts, not by assumptions, but with meaningful and substantiated data, intensifies.

As we consider the changing landscape brought on by the pandemic, it’s important to remember that other business risks continue to threaten business continuity. Natural and man-made disasters, as well as technology risks, abound. How can organizations stay prepared for these events? How can they develop a business continuity management (BCM) program that responds to all crisis types and scenarios? Who is the right person in the organization to own and manage the BCM program? And, what are the critical elements of a business continuity policy?
In Protiviti’s *Guide to Business Continuity & Resilience*, we answer these critical questions along with many other pressing questions about BCM and related practices. The complete fourth edition covers many areas, including:

- COVID-19 and large-scale disasters
- Business Continuity Management basics
- Ownership and governance
- Program and plan development
- IT Disaster Recovery and other technology considerations
- Third-party risk management and BCM
- Regulations, standards and guidance
- Testing, training and maintenance

Also in this edition is an appendix that includes a glossary of key BCM terms and definitions, links to regulatory information sources, and BCM program testing options. No one can predict when the next disaster or business disruption will strike; the only certainty is that something unplanned and disruptive will happen. Staying informed is the first step toward becoming prepared and building resilience for the unknown. Our goal is to help companies keep ahead of risks by building sustainable business continuity and resilience programs.

Q 4  What are some of the common lessons learned from large-scale natural disasters that organizations should be aware of when developing their own BCM programs? ..................................................................................................................... 2

BUSINESS CONTINUITY MANAGEMENT BASICS

Q 5  What is Business Continuity Management? .................................................. 5

Q 6  What is the value to an organization in designing and deploying BCM programs? ..................................................................................................................... 5

Q 7  BCM incorporates many different terms that appear to be very similar. What are the similarities and differences with some of the common terms? ..................................................................................................................... 6

Q 8  Is there a best practice approach to business continuity planning? ..................................................................................................................... 8

Q 9  What is the connection between operational resilience and business continuity management? ..................................................................................................................... 9

OWNERSHIP AND GOVERNANCE

Q 10 Who is the right person in the organization to own the BCM program? ..................................................................................................................... 11

Q 11 How do you structure an internal business continuity function or planning team? ..................................................................................................................... 11

Q 12 How do you convince executive management to fully support the organization’s business continuity efforts? ..................................................................................................................... 12

Q 13 What are the critical elements of a business continuity policy? ..................................................................................................................... 13

Q 14 What is the role for internal audit in the BCM process? ..................................................................................................................... 14

Q 15 How often should the business continuity program be audited? ..................................................................................................................... 14

PROGRAM AND PLAN DEVELOPMENT

Q 16 How has the Business Impact Analysis (BIA) process evolved? ..................................................................................................................... 16

Q 17 What are the most common approaches to executing a continuity risk assessment? ..................................................................................................................... 16

Q 18 What are some alternatives to performing an exhaustive BIA and risk assessment? ..................................................................................................................... 17

Q 19 Are there ways to make the BCM planning process more efficient and effective? ..................................................................................................................... 18

Q 20 What is the difference between crisis management and crisis communications? ..................................................................................................................... 19

Q 21 How do you integrate social media into the crisis communication strategy? ..................................................................................................................... 20

Q 22 Do you need business community management software/systems (BCMS) to develop an effective BCM program? ..................................................................................................................... 21

IT DISASTER RECOVERY AND OTHER TECHNOLOGY CONSIDERATIONS

Q 23 What are some of the key considerations when developing Information Technology Disaster Recovery (ITDR) strategies? ..................................................................................................................... 23

Q 24 What should disaster recovery planners consider when choosing primary and alternate sites? ..................................................................................................................... 23

Q 25 How is advancement of technology changing disaster recovery planning considerations? ..................................................................................................................... 24

Q 26 What are some key considerations for pursuing Disaster Recovery as a Service (DRaaS) or other disaster recovery (DR) vendor solutions? ..................................................................................................................... 25

Q 27 How can organizations leverage cloud services as a viable disaster recovery solution? ..................................................................................................................... 25

Q 28 How does switching to a cloud-based disaster recovery solution affect risk in the organization? ..................................................................................................................... 26

Q 29 What approaches are available when leveraging a cloud solution for disaster recovery? ..................................................................................................................... 26

Q 30 What are some key considerations for selecting and/or negotiating hosted solutions or disaster recovery support? ..................................................................................................................... 27

Q 31 What other requirements and recommendations should organizations consider as part of their IT governance practices? ..................................................................................................................... 28
Q 32  How do sourcing, outsourcing and procurement strategies impact business continuity and operational resilience?  30
Q 33  Why is it important for organizations to understand and assess their vendors’ business continuity plans and capabilities?  30
Q 34  What is the value of understanding and assessing vendors’ business continuity plans and capabilities?  31
Q 35  How should a business continuity program consider the impacts of disruption to vendor or supply chain partner operations?  31
Q 36  Should vendors’ business continuity plans and capabilities be tested? If so, how often?  32

REGULATIONS, STANDARDS & GUIDANCE
Q 37  How should regulations and standards shape the development of a BCM program?  34
Q 38  What specific guidance does the Federal Financial Institutions Examination Council (FFIEC) provide regarding BCM?  34
Q 39  What are ISO 22301 and ISO 22313?  35
Q 40  How does NFPA 1600 differ from more familiar BCM guidance?  35
Q 41  How does the COBIT standard address BCM?  36
Q 42  Describe the connection (if any) between the Sarbanes-Oxley Act (SOX) and business continuity.  37

TESTING, TRAINING & MAINTENANCE
Q 43  What are the prevailing practices regarding the storage of business continuity planning documentation?  39
Q 44  How often should business continuity-related documentation be updated, and how can organizations keep the plans current?  39
Q 45  How often should BCM plans be tested?  40
Q 46  What testing options are available for BCM programs?  41
Q 47  Should organizations expand testing beyond IT?  41
Q 48  What are some successful business continuity training approaches?  42
Q 49  How does BCM awareness differ from BCM training?  43
Q 50  What certification options are available for BCM practitioners?  43

INDUSTRY-SPECIFIC CONSIDERATIONS: FINANCIAL SERVICES
Q 51  What regulatory guidance and standards should financial institutions rely on?  45
Q 52  How has U.S. regulatory guidance on business continuity changed in recent years?  46
Q 53  What is operational resilience and how is it relevant to business continuity for financial institutions?  46
Q 54  How should firms consider third party-related risks as a component of business continuity management?  46
Q 55  Are financial institutions, such as banks, required to recover disrupted operations within a defined time period?  47
Q 56  Are business continuity standards for financial institutions set only by the regulatory agencies?  47
Q 57  To what extent are financial institutions responsible for the business continuity of vendor-supported systems?  48

INDUSTRY-SPECIFIC CONSIDERATIONS: HEALTHCARE
Q 58  How can healthcare organizations ensure their emergency preparedness plans meet current regulatory requirements?  50
Q 59  Does the Health Insurance Portability and Accountability Act (HIPAA) include a requirement to implement BCM processes?  52
Q 60  Does The Joint Commission require business continuity planning for hospitals?  52

INDUSTRY-SPECIFIC CONSIDERATIONS: TECHNOLOGY, MEDIA AND TELECOMMUNICATIONS
Q 61  What are some of the supply chain considerations for Technology, Media and Telecommunications (TMT) organizations?  54
Q 62  How should TMT organizations address or revamp their research and development programs to ensure business continuity?  54
Q 63  What are some other key considerations for TMT organizations to address as part of their business continuity planning?  54
Q 64  What are the best practices for ensuring the availability of critical infrastructure for the communications industry?  55
Q 65  What are some key considerations in incident management planning for the communications industry?  56
Q 66  What are some vendor-related technology considerations in business continuity planning for communications organizations?  

Q 67  What are some of the key technology-related challenges faced by communications organizations in maintaining an effective business continuity program?  

INDUSTRY-SPECIFIC CONSIDERATIONS: CONSUMER PACKAGED GOODS/RETAIL  

Q 68  What is the impact of omnichannel strategies on the business continuity plan?  

Q 69  Do the organization’s business recovery strategies consider stock keeping units (SKU) optimization?  

Q 70  How should global trade tensions be considered in the BCM program?  

Q 71  Should customer service be included in a business continuity plan?  

INDUSTRY-SPECIFIC CONSIDERATIONS: ENERGY/UTILITIES  

Q 72  Can business continuity management planning account for complex, international supply chains that can be disrupted by geopolitics?  

Q 73  Should field sites and operational plants have their own business continuity plans?  

Q 74  Why is having a business continuity program in place especially important for the energy industry?  

Q 75  What type of outages should energy and utility organizations plan for?  

INDUSTRY-SPECIFIC CONSIDERATIONS: MANUFACTURING  

Q 76  How can pursuing a single-source supply strategy affect your organization’s overall risk of business interruption?  

Q 77  Has management designed manual backup procedures to carry out manufacturing schedules and order releases?  

Q 78  How do companies that rely solely on single-site manufacturing or centralized operations plan for the impact of a long-term outage?  

Q 79  How do companies that utilize just-in-time inventory production methods ensure continuity in operations during disruptions?  

Q 80  How can manufacturers that utilize third-party co-manufacturers ensure minimal disruptions from these organizations?  

Q 81  Where does a product recall procedure fit into a BCM program?  

INDUSTRY-SPECIFIC CONSIDERATIONS: GOVERNMENT  

Q 82  Are there any special or unique considerations for government organizations with regard to business continuity planning?  

Q 83  What are some common challenges or gaps that government organizations may need to consider as part of their business continuity planning?  

Q 84  What actions can government organizations take to remedy these gaps?  

APPENDIX  

Glossary

Testing Options
COVID-19 AND LARGE-SCALE DISASTERS
Q1  Considering the COVID-19 pandemic, what role should business continuity management (BCM) programs play in pandemic planning and response?

Pandemic planning or preparedness is an important part of business continuity planning. As COVID-19 has shown, pandemic preparedness presents unique challenges for businesses, given its far-reaching geographic impact and difficulty with predicting its scale and duration. It can also have a wide range of impacts on businesses (e.g., worker displacement, technology constraints, decreased production, and challenges with third-party capabilities). Below we list a few of the critical roles BCM can play in pandemic planning and response:

- During a pandemic response, BCM should ensure the crisis management function remains engaged, particularly as it relates to following a defined protocol and crisis communications. Following a defined protocol that also can be flexible to the fluidity of any disruptive situation is key to a successful response. Since a pandemic can cause the workforce to be dispersed, which can lead to feelings of isolation and disconnectedness among employees, teams and even third parties, crisis communications can and should include strategies for both internal and external audiences.

- The business continuity program provides critical information that can be utilized as key inputs to the pandemic response plan. Similar to other plans (e.g., business resumption and IT disaster recovery plans), the contents of a pandemic response plan should be informed by foundational activities such as the business impact analysis (BIA) and continuity risk assessment. Outputs of these efforts should include elements such as the criticality of business processes, expected impact to the business caused by a disruption, and maximum tolerable downtime. This information can be used to shape or inform a company’s response.

- Another important data element that can be useful to pandemic response is the identification of critical third parties essential for each business process to function. These critical third parties can be identified during the BIA, along with the resulting impact if they are disrupted or unable to provide products and services. This information will serve as a guide to develop subsequent strategies and planning discussions.

- Business continuity planning often requires developing playbooks that contemplate a variety of events or disasters that can impact the business, and then outlining how organizations should respond during and/or after those events or disasters. These playbooks can take the form of checklists or detailed step-by-step procedures and plans, and are typically scenario agnostic (i.e., an all-hazards approach). The most effective way to manage the impact of a pandemic, or any other crisis or disaster, is to implement playbooks that have been developed as part of a mature business continuity program.

Q2  What are some key business continuity considerations or priorities when developing a pandemic response, and what lessons have we learned so far from COVID-19 that would inform future business continuity planning?

The health and safety of personnel, the welfare of customers, and concerns about other human life should be the priority. Continued operation of the business, or maintaining or preserving business assets, must be secondary to preserving human life, health and safety. Once this is addressed, attention can shift to a more traditional risk management process, which focuses on the key people, processes and technology driving the business. Following are some key considerations when developing a pandemic response:

- It is important to understand the key business objectives and which pandemic-related risks could impact your ability to meet those objectives. Having a firm understanding of your business objectives allows you to focus your time, resources and attention on mitigating those risks to an acceptable level.
For a protracted event such as a pandemic, it is essential to have an ongoing and evolving process for identifying, tracking and managing risks. As new risks emerge or existing risks evolve, companies should continue to monitor those changes and adjust their responses accordingly.

Organizations should revisit the results of any previous business impact analysis to determine whether the perceived impact pre-pandemic was accurate, particularly as it relates to process dependencies, key personnel risks, key third parties and critical applications.

Comparing the previously established impact tolerance to the actual impact experienced during a disruption, and using that comparison to recalibrate the organization’s true impact tolerance, can help the organization enhance its strategies and plans going forward.

The nice thing about business continuity planning is that the discipline is ever evolving. Most organizations have already launched after-action activities — even though the COVID-19 crisis is not over yet — to understand what happened, what was learned from it and what should change about their response so they can be more effective if it ever happens again.

Q 3 How should your BCM program provide support for returning to normalcy post-pandemic?

The core building blocks of any good BCM program are business resumption, crisis management and IT disaster recovery. Each plays an important role in a business continuity lifecycle, which extends beyond the duration of an event. It also addresses how organizations return to normalcy after the event. As an example, the crisis management team formed during a crisis to make critical business decisions in a timely manner that will direct and guide the response is the same team that will guide activities to restore normal operations.

Simultaneously, the group of IT professionals who executed an IT disaster recovery program that allows, for example, an entire workforce to go remote all at the same time, along with all of the bandwidth and infrastructure implications necessary to make that a possibility, are also responsible for helping that same workforce return to normalcy.

Q 4 What are some of the common lessons learned from large-scale natural disasters that organizations should be aware of when developing their own BCM programs?

Regardless of what causes a disruptive event, the “signature” of that event is unique unto itself. The same is true for outages caused by environmental or natural events, such as hurricanes, pandemics, etc. As such, the detailed lessons learned will be specific to each company based on the products or services they provide, geography in which they operate, which locations may have been impacted, and the nature of the disruption and its impacts. There are general lessons learned from these events that can apply to most every organization.

Communications — At the top of most lessons learned from an event is the need to ensure appropriate communication to employees, executives, key internal stakeholders and third parties. Communication mechanisms must be well-vetted and familiar before an event occurs for communication to be effective during and after an event. While email seems ubiquitous, especially when hosted in a cloud environment, other communication mechanisms may be necessary. Many organizations are utilizing Emergency Mass Notification Systems or EMNS (e.g., AlertMedia, Everbridge, OnSolve) to utilize personal and business-related email, text messaging and phones to contact employees and obtain immediate confirmation of their well-being. This is especially important when people are forced to disperse and life-safety considerations are critical. Developing communication teams for internal and external audiences, rehearsing roles and responsibilities, and testing related systems are all valuable exercises that provide a baseline for senior management to use as it makes decisions following an event.
• **Availability of employees** — Most business continuity planning assumes employees will return to work to support business recovery; however, employees without a strong economic incentive who are forced to evacuate an area for an extended period are less likely to return. Ensuring employees can work remotely and connect to necessary systems is essential and practically a necessity for most organizations. If employees are simply not available, basic cross-training of critical processes should be performed to ensure there are no single points of failure related to critical personnel.

• **Employee assistance plans** — Since employees’ first concern naturally will be for their families and their homes, developing and communicating an assistance plan for a disaster is both compassionate and pragmatic. Companies that provide material assistance for affected employees will find that their workers are able to return to their jobs substantially earlier than if they had not received assistance. These plans will likely need to be tailored to fit the event and the specific issues facing their employees.

• **Proactive evacuation** — It is not uncommon for people to spend 24 hours or more trying to leave a pending disaster area. When a hurricane or other disaster is imminent, businesses may want to encourage their employees to err on the side of caution and relocate early. This increases the likelihood that workers will be able to obtain hotel rooms or other accommodations near the business recovery site and that they may retrieve all necessary materials and equipment before they evacuate.

• **Supporting infrastructure services** — Basic services such as utilities, trash collection and publicly accessible healthcare can be interrupted for an extended period. Frequently, following regional disasters, some organizations recover their own operations only to find the supporting infrastructure, sanitation, utilities, mass transit, telecommunications, hotels, restaurants, etc., are not as well prepared. Organizations should determine in advance how they will compensate for the absence of such services, including contracting with third-party vendors in the private sector to provide these basic services to employees until supporting infrastructure services resume.

• **Decentralized critical processes** — Companies located in disaster-prone regions whose critical processes (e.g., information systems, call centers, distribution centers, manufacturing) are concentrated in the region may find that they have lost — and therefore have to recover — everything. Companies that have decentralized their processes may find that while one area is affected, other critical processes remain operational and can support customers and sites affected by the disaster.

• **Testing and exercising** — Many organizations with plans to relocate people and resources have never tested them in preparation for a disaster of regional scope. Some plans fail to consider the competition for everyday resources (e.g., rental cars/trucks, hotel rooms, shipping providers) which occurs after a massive event, or they fail to consider the difficulty in obtaining custom or highly specialized equipment, such as in the manufacturing industry. Others identify in general terms the types of people, vital records, and equipment they would like to relocate, but do not have a system to quickly identify, gather and transport these resources. Businesses also must anticipate and plan for secondary damage (e.g., flooding, fires, theft). This includes obtaining the appropriate insurance to assist with recovery.

• **Actionable plans** — When disaster strikes, it is not uncommon for businesses to ignore their plans. This is because plans might be too general, overloaded with detail, or unfamiliar to the personnel intended to use them during the crisis. Companies should diligently read through and critically evaluate the information contained in their plans and ensure the information is complete, accurate, comprehensive and actionable. This will help ensure the plan reflects the current state of the business and can serve as a useful guide during a disaster and its aftermath.

• **Emergency funds** — Disaster events prove that the adage, “cash is king,” is still correct. In the absence of infrastructure to process credit cards or other forms of electronic payment, cash is still the most effective way to acquire resources — especially those in short supply and high demand. Companies should consider how cash will be made available in a secure fashion to meet the needs of the business continuity effort.
What is Business Continuity Management?

Business Continuity Management (BCM) is the design, development, implementation and maintenance of strategies, teams, plans and actions that provide protection over, or alternative modes of operation for, those activities or business processes which, if they were to be interrupted, might bring about seriously damaging or potentially significant loss to an enterprise. As BCM has evolved, the threat landscape has grown considerably to include both internal and external events, as well as extreme-but-plausible incidents.

BCM consists of three core disciplines:

- **Crisis management and communications** — This discipline enables an effective and cohesive response to an event. Crisis management processes focus on stabilizing the situation and supporting the business if alternate modes of operation are needed, using effective planning, leadership and communication protocols.

- **Business resumption planning or business recovery planning** — This discipline focuses on disrupted aspects of business functions and processes that relate to or support the delivery of core products or services to a customer. Business resumption processes focus on the evaluation of people, processes, technology and other resources vital to the organization’s operations. The objective of business resumption planning is to mitigate potential impacts from disruptions, regardless of the cause, by developing plans that guide personnel through operations with diminished capabilities and toward business as usual.

- **IT disaster recovery (ITDR)** — This discipline addresses restoration of critical IT assets, including systems, applications, databases, and storage and network assets. An ITDR strategy also should encompass all technology service provider (TSP) relationships (e.g., cloud service providers, SaaS partners) to ensure that all technical stakeholders remain aligned.

In addition to the traditional BCM disciplines listed above, many organizations manage other closely related programs as part of their overall BCM program. These programs include:

- **Incident management (or incident response)** — This term commonly refers to identifying, analyzing and managing the response to a disruptive event. Regardless of nomenclature, incident management programs typically include emergency response measures such as evacuation of facilities, first-aid response and first-responder interactions.

- **Cybersecurity incident response** — This is specific to the planning for, response to and recovery from a cybersecurity incident such as a data breach, a phishing attempt or a distributed denial of service (DDoS) attack.

Finally, due to the nature of business continuity, it is common for several functions to be integrated at various phases of business continuity planning. For example, facilities or physical security teams may engage in emergency management activities, and safety and environmental health teams may have input in developing recovery strategies. Integration of these enterprise-impacting functions, depending on the organization or industry, can be confusing.

What is the value to an organization in designing and deploying BCM programs?

The value of BCM lies in risk mitigation — minimizing the risks associated with any disruption to business as usual. In the wake of recent catastrophic natural disasters and the COVID-19 pandemic, business leaders are more mindful than ever of the need to plan for and respond to business disruptions.

The business environment is fraught with risks that can impact businesses’ ability to not only continue operations, but also protect their people and brand, earn revenue, maintain relevance and remain compliant with regulations. Companies need to stay ahead of these risks by understanding priorities, planning for disruptions, employing good business practices and exercising forethought to increase their ability to course-correct quickly when things go wrong.

Organizations realize value when they proactively design and deploy business continuity solutions to manage a specific risk or multiple risks. For example, understanding and
developing contingency plans for the loss of a key supplier can help a business mitigate potential financial, operational and reputational impacts.

**Financial risk** — This is the most evident and quantitative area of risk. Companies can minimize financial loss and maintain market share by focusing on several factors, including:

- Responding to customer demands and maintaining a viable supply chain
- Understanding officer liability
- Inventorying potential replacement loss (i.e., the cost of replacing damaged assets)

To protect the supply chain and ensure that supply keeps up with customer demand, a company may hold its suppliers accountable for disruptions to the supply chain that impact its operations. For example, a company can use contract provisions to hold a supplier accountable for timeliness in delivery of products or services, as well as for quality of products or services delivered.

A company can implement BCM solutions to minimize the potential for huge unexpected costs stemming from single points of failure and critical external dependencies. For example, if a company depends on a single critical supplier that suddenly is unable to provide core products or services, a well-designed BCM solution would provide contingencies to mitigate the financial loss.

**Operational risk** — This area of risk stems from the inability of companies to produce core products and services as expected. This can include risks associated with equipment or technology obsolescence, a failure in internal functions, and unexpected changes to a leadership team. Other operational risks directly impacting business as usual include:

- Loss due to failed single points of failure and critical external dependencies
- Productivity loss (employees unable to perform their jobs for any period)
- Response loss (cost of time/materials required to respond to the disruption)

A company should implement BCM solutions to minimize operational gaps and ensure that the delivery of products and services continues, even during unusual circumstances. Comprehensive implementation of a BCM program will lower risks associated with readiness, planning and response, which can decrease overall operational risk.

**Regulatory risk** — Regulatory bodies are increasingly holding companies accountable for maintaining validated capabilities, teams and plans, and can issue fines to those that operate without a BCM program. Depending on the regulator, a repeated and unmitigated issue at a regulated entity could result in a reportable item, which could impact the company’s creditworthiness or reputation. Generally, companies that violate regulations or compliance requirements face:

- Fines, penalties and judgments
- A Matter Requiring Attention (MRA) or similar rebuke from a regulatory body, which could invite an additional level of scrutiny or a higher expectation of performance

**Reputational risk** — Bad press can cause a decline in revenue, unwanted social media attention, lower market capitalization and, in the long term, a negative opinion of an organization in the eyes of the discerning public. In today’s 24-hour news cycle, a measured, empathetic, rapid and relevant response to any event is crucial to maintaining a positive reputation.

A mature BCM program drives value by protecting a company’s brand and adeptly managing the ever-changing business landscape in the face of growing competition.

---

**Q7**  
**BCM incorporates many different terms that appear to be very similar. What are the similarities and differences with some of the common terms?**

One of the more confusing aspects of BCM is its terminology. The confusion is mostly due to differences in how regulators and industry groups use and define terms in the BCM lexicon. Below are a few examples grouped according to the core discipline to which they are most aligned.
Crisis Management and Communications

- **Continuity of operations plan (COOP)** — Federal government agencies and entities typically use this term to establish policies and guidance for essential functions related to a broad range of events and disasters.

- **Emergency management and operations** — This phrase is commonly used in the healthcare field, particularly in the clinical (i.e., patient-facing) side of contingency planning. It is sometimes used interchangeably with “crisis management” in other industries, but typically as a reference to the initial response aspects immediately following an event.

- **Emergency response** — This term refers to the immediate actions taken to preserve life and safeguard property and assets, often a subset of a broader crisis management program. A building evacuation plan is an example of an emergency response component.

- **Incident management and response** — This is often used interchangeably with “crisis management.” It is also commonly used to refer to responses to any number of events impacting a particular entity or location, such as a hurricane on the Gulf Coast, an earthquake in California or a supply chain disruption for a logistics provider. Recently, firms have been developing incident response plans as part of their crisis management programs to leverage the shared, high-level protocols associated with escalating and reporting an event. This strategy enables companies to quickly and efficiently put into action predefined plans designed for scenarios that may impact a function or facility.

- **Major incident management (MIM)** — This term refers to a response program for serious interruptions of business activities. It is frequently used interchangeably with “crisis management.”

- **Resilience** — This is an evolving concept that refers to the ability of companies to withstand and quickly adapt to disruptions while attempting to maintain continuous operations. Resilience focuses on preserving business services and relies on regular maintenance to ensure that the entire business operation, or process or function, maintains its ability to remain flexible in all circumstances. Recently, this term has been used to describe a focus, such as technology resilience, business resilience and cyber resilience.

Business Resumption Planning

- **Business recovery planning** — This term refers to various steps taken for an individual process or business line as it relates to the planning of inputs/outputs, personnel resources, information technology and physical work locations in the aftermath of a disruption. This term is often used interchangeably with “business resumption,” “contingency planning” or “business continuity planning.”

- **Business continuity planning (BCP)** — This term is used to denote the planning aspects of business continuity management (BCM). BCM usually refers to the comprehensive program, while BCP is the predefined set of steps taken to recover a business process in the event of a disruption. This term is often used interchangeably with “business resumption,” “contingency planning” or “business continuity planning.”

- **Business resumption planning** — This process focuses on recovery of business functions. The term is often used interchangeably with “business recovery,” “contingency planning” or “business continuity planning.”

- **Contingency planning** — This phrase refers to the set of tactical steps a team or function may take to resume a disrupted process. Often the term is used interchangeably with “business recovery,” “business resumption planning” or “business continuity planning.”

IT disaster recovery (ITDR)

- **Disaster recovery** — This is a term reserved for recovery and resumption of critical technology assets in the event of a broad and unplanned outage. Disaster recovery can include tasks such as resuming individual systems or recovering all critical aspects of the IT environment. Disaster recovery is a component of an overall BCM program.

(Note: The above list is not comprehensive. The practices within a specific industry or regulatory landscape may influence how BCM terminology is used.)
Is there a best practice approach to business continuity planning?

Although vague, this frequently asked question is a valid one. BCM approaches and scopes vary widely; one size does not fit all. The primary driver of a BCM program should always be the recovery requirements (and constraints) of the business. However, several recommended attributes or program characteristics should be integrated into every BCM program. The process of embedding each of these into the program may vary:

- **BCM program governance** — This involves identification and formalization of the BCM steering committee and executive-level risk management oversight to determine BCM program requirements.

- **BCM program and implementation design** — This includes definition of policies, standards and tools to support business continuity efforts. In addition, an effective BCM program should define the operating model, which includes who is accountable and responsible for each key discipline of the program (e.g., crisis management, business resumption and IT disaster recovery), technology tools used to monitor and manage the program tasks, and any defined key risk indicators (KRIs) and key performance indicators (KPIs).

- **Business impact analysis (BIA)** — The BIA, a type of risk assessment that serves as the foundation of a BCM program, enables organizations to capture and effectively measure the potential business impacts of a disruption (i.e., operational, reputation, financial, regulatory or compliance impacts). The objective of the BIA is to establish recovery priorities for business processes and the resources (i.e., technology, workspace, equipment, personnel and third parties) on which each of those processes rely.

- **Risk assessment** — In BCM parlance, this may be referred to as the continuity risk assessment (CRA), which includes identification and prioritization of threats and failure scenarios to which the organization may be vulnerable. The CRA is not an enterprise risk assessment (ERA). Rather, the scope of the CRA encompasses those scenarios that pose a direct risk to operations (e.g., a supply chain disruption, a technology outage, a data breach, or severe weather in a densely populated area where operations reside).

- **Strategy design and implementation** — Identification and implementation of continuity strategies that best meet the organization’s needs, based on a cost-benefit analysis and operational risk tolerance, is crucial. The results of the CRA and the BIA should inform the design of the recovery strategies.

- **Plan documentation** — Following the design of a viable recovery strategy for a particular risk, the response, recovery and restoration procedures should be documented to enable effective business continuity operations. Each discipline employed (i.e., crisis management, business resumption and IT disaster recovery) should have a documented strategy and plan.

- **Testing** — A BCM program that is not tested regularly cannot be confidently relied on. Testing and continuously improving the validity of business continuity strategies and corresponding teams and plans are critical. Rigorous testing of each key discipline’s teams and plans, both separately and in tandem, should be conducted to ensure confidence in the BCM program.

- **Training and awareness** — An organization is better prepared operationally if its employees are knowledgeable about their respective roles and responsibilities regarding business continuity activities. Training should be provided to all employees, including those directly responsible for response/recovery team efforts, as well as to those not directly engaged on a recovery team.

- **Compliance monitoring and audit** — Conducting regular and objective reviews of the BCM program allows for program changes, if needed, while following a reasonable cadence. Also, the reviews will enable easy-to-maintain compliance with internal and third-party business continuity standards.
What is the connection between operational resilience and business continuity management?

Regulators around the world are developing new rules and expectations aimed at strengthening the operational resilience of the financial services sector, an effort being spearheaded by supervisory authorities in the United Kingdom. Operational resilience defines the ability of an organization to withstand adverse changes in its operating environment and continue the delivery of business services and economic functions. Below are the various approaches through which an operational resilience program can enhance and extend traditional BCM practices and concepts.

- **Identifying important business services** — These include most critical product suites or lines of business that may directly impact end consumers any time there is a disruption (e.g., ATM accessibility interruption or degraded payment processing).

- **Setting impact tolerance** — Under traditional BCM programs, risk appetites are not easily quantifiable, and most risk appetite statements lack forward-looking metrics or documented thresholds for triggering actions (e.g., containment options) in a crisis. Under operational resilience, institutions are expected to develop quantitative impact tolerances for each important business service.

- **Testing** — Testing various aspects of a BCM program and capabilities is typically discrete and segmented within the IT, operations or crisis management teams. In most cases, these tests are not scoped or facilitated in a manner that validates all aspects of the function or line of business being tested. Under operational resilience, institutions are expected to test extreme-but-plausible scenarios to better understand realistic recovery times versus established impact tolerance. Additionally, full scenario testing is key to helping institutions identify areas of failure or vulnerability, as well as concentration risks that could result in a business disruption. Testing will also indicate where investment in technology or processes is needed to stay within established tolerances.

- **Mapping** — Front-to-back process mapping and more comprehensive and integrated testing activities are essential elements of an effective operational resilience program. Though process mapping has been recommended for years, accuracy and completeness are not regularly enforced. Under operational resilience, front-to-back mapping is expected to help institutions better understand what constitutes an important business service. Institutions can use mapping to:
  - Identify people, skill sets, processes, technology, data, third parties, operations, reporting requirements and legal entities, along with clearly defined cross-functional/business dependencies and handoffs.
  - Identify important business services and rank them in order of priority or criticality.

- **Understanding economic impact across stakeholders** — Beyond identifying their own important business services and setting impact tolerance, organizations are expected to demonstrate a firm understanding of the impact of an adverse event on the financial sector and the broader economy. For example, banks must look at all upstream and downstream impacts, employ a systemic look at potential service degradation scenarios and how they may need to prioritize clients and channels, and consider the effects of prolonged disruptions or outages. Under most traditional BCM programs, there are no formal or consistent definitions of important business services, testing or severity levels.
OWNERSHIP AND GOVERNANCE
Q 10  Who is the right person in the organization to own the BCM program?

As organizations begin to develop their BCM program capabilities and plans, they are confronted with a common question and dilemma: Who should own the overall program? A successful BCM program requires various levels of accountability and responsibility within an organization. While some organizations may ultimately decide to create a separate business function or unit to own the program, many choose to utilize existing resources and/or personnel.

Organizations typically provide leadership to the BCM program through one of three roles: sponsors, owners or custodians. Sponsors provide and ensure organizational and financial support. Given that consistent visibility to the board and senior leadership is essential, sponsors should be executives. Owners have direct accountability or are responsible for ensuring support and overall program execution. BCM owners are department leads with an understanding of strategy and direct working relationships with those implementing the annual plan and managing day-to-day tasks. Finally, custodians have the primary responsibility for coordinating BCM tasks executed throughout the organization. Custodians understand the various roles needed for each aspect of a comprehensive program and are empowered to escalate a concern in a timely and coherent manner.

It is not uncommon for these oversight roles to be aligned to the respective BCM discipline. For example, the CTO, CIO or CISO may own the IT disaster recovery program, and the head of marketing may own crisis management. It is common for organizations to have a BCM steering committee or other similar decision-making and governance group providing oversight.

There is no single recommended structure for a BCM program. The nuances of a company’s industry, risk profile, culture and operations can influence the decision about where the BCM should reside. Some examples include:

- **Finance** — The CFO’s function or vertical.
- **Executive council** — A subset of the senior management team, which may include the general counsel and the directors of human resources or corporate communications.
- **Operations** — The COO’s function or vertical.
- **Risk management** — The CRO’s function or vertical; this is most common, as a designated and qualified business continuity practitioner would align most directly within an operational risk program.
- **Information technology** — The CTO’s, CIO’s or CISO’s organization or vertical.

As a matter of practice, it is recommended that BCM program ownership be maintained at an executive level within the organization so that it remains visible to decision makers and influences enterprise adoption while supporting all aspects of a mature program.

Q 11  How do you structure an internal business continuity function or planning team?

The size and composition of an organization’s business continuity function depends on various characteristics of the enterprise, including:

- Total employee headcount
- Number and geographic dispersion of company locations
- Similarity of operations between business departments, subsidiaries and organizational units
- Degree to which management oversight and leadership are centralized versus decentralized
- Risk profile of the organization (e.g., highly regulated, governed by external oversight bodies)

While it is common for companies to have a few individuals responsible for the organization’s overall business continuity efforts, many businesses have realized that maintaining an effective BCM program truly takes a village. Nobody knows the intricacies of a particular department or underlying business processes like the respective leaders and their supporting team members who are the “boots on the ground.” As such,
when it comes to ensuring that a business impact analysis or a resumption plan for a department is current and actionable, the BCM lead (or leads) must solicit input and involvement from those individuals on the ground.

Similarly, a BCM lead must act as a conduit for relaying important recovery priorities to the IT organization and for ensuring that relevant IT disaster recovery plans and supporting technologies are in alignment with the recovery needs of the business. In industries like manufacturing or energy and utilities, where operational technology is not managed in the same manner as the enterprise or corporate aspects of an IT organization, specialized knowledge may not be readily available. These organizations or industries may have critical resiliency and recovery requirements that a BCM lead can help identify and prioritize. Further, the BCM lead can influence how subsequent recovery planning documentation addresses those priorities.

BCM leads must have clearly defined roles and responsibilities, as well as the support and sponsorship of the executive management team. Further, in many organizations, it is not uncommon for some BCM responsibilities to be delegated to several levels of personnel. If this occurs, executive sponsors should be engaged to ensure that all stakeholders remain aligned and that the needs of the organization are the focus when the time comes to manage all aspects of the program.

From an operation model standpoint, BCM programs can be organized into one of three primary models: centralized, divisional and federated.

• **Centralized** — Under this model, a central continuity office serves the business units by providing policy, guidance, tools, templates, metrics and maintenance.

• **Divisional** — Multiple continuity offices serve the different region and business lines.

• **Federated** — A central continuity office, linked to various centers of excellence, provides dedicated services to different regions and business lines.

Q12 **How do you convince executive management to fully support the organization’s business continuity efforts?**

When not a compliance need, BCM is often viewed as discretionary, since the value of time and resources spent planning, training, documenting, testing and validating all aspects of a program cannot be realized until something truly goes wrong. In the absence of regulatory requirements, audit findings or specific customer demands, the most effective way to convince executive management to fully support BCM efforts is to conduct and share results from an exercise that highlights risk (e.g., the business continuity risk assessment and business impact analysis, or BIA). Results from the exercise, which typically include recovery priorities, corresponding recommendations and industry benchmarking data, should provide executive management a complete view of the organization’s business continuity needs.

Communicating the value of business continuity efforts to executive management can also be accomplished through a cost-benefit analysis. The cost analysis addresses the funding and resources necessary to add resiliency and recoverability to key areas of the existing business and technology environment, while the benefit analysis relates to avoiding the potential impacts of a disruptive event (e.g., revenue loss, downtime, property damage and reputation degradation).

Another data point that can be shared with executive management is business interruption premium savings from the organization’s insurance provider as the result of implementing a tested BCM program. Program implementation can also help firms realize savings in the cost of procuring directors and officers (D&O) liability insurance. From a fiduciary perspective, if the directors and officers understand that they can be held personally liable for the organization’s response to a business interruption, they are more likely to support and enforce BCM. Additionally, it is becoming more common for customers to require (as part of the contract) that their suppliers and business partners have a business continuity plan in place. A company may hold its suppliers accountable to maintain continuity plans and protect its supply chain. It is now common practice for customers to have a vendor...
A growing number of organizations are developing formal, documented business continuity policies to support their BCM programs. Typically, the content and format of the policies differ based on existing standards and the culture of the organization. Below are the critical elements of a business continuity policy:

- **Accountability** — Identifies the executive or executives accountable for BCM program planning and execution, as well as those responsible for resourcing and strategy decision-making.
- **Roles and responsibilities** — Establishes roles and responsibilities for all employees regarding planning and activities before, during and after a disaster.
- **Program scope** — Defines program tenets and recovery priorities via the continuity risk assessments and a business impact analysis. Further, this foundational effort establishes the criteria for the type and scale of incidents to be addressed in the BCM program.
- **Recovery strategy development** — Identifies specific actions necessary to develop relevant and right-sized strategies to enable preparation for, response to and recovery from impactful events. Recovery strategies should be developed to mitigate impacts from the loss of key personnel, key processes and technology, or primary workspace and facilities.
- **Plan development and maintenance** — Specifies the standards regarding the review and maintenance of all program and planning documentation.

Finally, lessons learned from other companies carry a lot of weight with leaders. Business continuity actions taken by other organizations (of a like size or in the same industry) often drive action or increase maturity in others. This is particularly the case if an organization successfully recovered from a perceived catastrophic failure (although the opposite also can be true).

Q13 **What are the critical elements of a business continuity policy?**

- **Testing (exercising)** — Defines the various types, frequency and required participants (e.g., internal employees and external business partners or third-party service providers) of testing activities. Planning of each discrete exercise (e.g., defining scope, objectives and success criteria) and capturing test results should also be enforced by policy.
- **Training and awareness** — Establishes standards for role-based training of personnel named in the response and recovery plans, as well as general awareness for employees affected by the business continuity strategies.
- **Legal, regulatory and contractual assessment** — If applicable, captures the organization’s understanding of legislation, regulation and industry standards, as well as customer contractual requirements impacting business continuity requirements.
- **Internal audit participation** — Defines the role of internal audit in the planning process and/or the review of compliance with the requirements set forth in the BCM policy.
- **Reference** — Provides linkage to a glossary, industry source, standards, guidelines, regulations and policies that the BCM program relies on within the organization.

These key elements of a business continuity policy will assist an organization's planning team with gathering the necessary support and resources to manage the BCM program effectively.
Q 14  What is the role for internal audit in the BCM process?

Due to their perspective, exposure to all areas of the organization, and associated influence, internal audit departments are well-positioned to add considerable value in terms of BCM. Here are several ways the third line of defense can make an impact:

- **Act as an internal salesperson** — Support the business case for business continuity through participation in the risk assessment and BIA processes (tasks that internal audit may address through the development of annual audit plans).

- **Ensure creation and maintenance of business continuity policies** — Because of its familiarity with policies, controls and the key components associated with BCM processes, internal audit can assist with the development of initial policies and standards (in line with reasonable maturity levels and business objectives).

- **Maintain project management standards** — Similar to the development of business continuity policies, internal audit is typically familiar with project management standards and project risk management programs.

- **Understand fluid landscape** — In addition to encouraging the development of a comprehensive program (i.e., governance, business and technology), internal audit can assist in the necessary maintenance efforts of all program components, as opposed to a sole focus on plan documentation. Specific attention should be paid to the planning and execution of business continuity tests and exercises as teams, plans and recovery strategies evolve. Internal audit should observe such tests and ensure anomalies are addressed.

- **Encourage continuous improvement** — Based on familiarity with internal and industry standards/requirements, internal audit is positioned to regularly review the planning process and strategies to ensure compliance. Internal audit also can remain engaged through the development of recommendations to address opportunities for improvement.

Because BCM is a management-owned process, internal audit can be an active participant and adviser to the organization’s business continuity executive sponsor and steering committee.

Q 15  How often should the business continuity program be audited?

The answer is organization specific, based on the internal standards, regulatory requirements and changes to the business. In most cases, an audit should be conducted every 12 to 24 months to ensure compliance with internal policies and procedures, with emphasis on the execution of testing, training and maintenance activities. In a growing number of firms, internal audit is an observer of all major testing activities, as opposed to a reviewer of test summary documentation. As such, the frequency of audit-related activities increases.

The Institute of Internal Auditors (IIA) published Global Technology Audit Guide (GTAG) 10: Business Continuity Management (most recently updated in 2014), which states that BCM-related audit activity should take place “on a regular basis” and can include:

- Playing a role in the organization’s planning, to include the risk assessment. (It is typical for internal audit to help with an assessment of an organization’s internal and external environment.)

- Evaluating the business continuity and disaster recovery plans during the planning and development phases. (Internal auditors have a thorough understanding of the business and the individual functions and interdependent relationships and can contribute to the BCP process.)

- Reviewing the proposed business continuity and disaster recovery plans for design, completeness and overall reasonableness/viability.
PROGRAM AND PLAN DEVELOPMENT
Q 16  How has the Business Impact Analysis (BIA) process evolved?

The BIA is used to identify and prioritize an organization’s business processes and supporting dependencies, as well as how long each business process can operate in a degraded state before irreparable harm is caused. The BIA process is constantly evolving, but the manner by which each process is measured should include an assessment of the collective impacts from operational, financial, reputational, and regulatory and compliance standpoints.

A primary metric gathered as part of the BIA is the Recovery Time Objective (RTO), expressed in time and captured for each process and associated technology dependency. The use of metrics like the RTO has been a part of the BIA for years. As operations and technology continue to become more integrated, critical processes rely on technology, thereby causing that technology to be critical. These dependencies highlight complexities requiring analysis and the need for a tailored and flexible approach particular to the operational environment.

In the past, practitioners used BIAs to explore a range of possible threats to an organization. However, more recently, the BIA has adopted an event-agnostic approach, meaning it is more common to focus on possible impacts of a disruption on each business process. The collective impacts on the organization become the driver, rather than the triggering event, for the development of recovery strategies and planning. Further, current best practice is for process owners, information technology teams and the executive team to agree on the resultant RTOs for each critical process and supporting technology.

A facilitated BIA with interviews and discussions is recommended. Ideally, the person or team responsible for business continuity management leads all BIA discussions. Questionnaires without facilitation can introduce bias or cause confusion if respondents are unclear about terminology used in the printed questions. The quality of data gathered from questionnaires also suffers when participation is low or when the number of responses from a particular group is disproportionate.

The quality of the BCM program, which is significantly influenced by the BIA, can benefit from having objective experts trained in best practices. BCM experts with facilitation experience can guide process owners to develop meaningful and realistic RTOs. They can then apply BCM and industry best practices (e.g., supporting organizations with data collection, validating analyses, and documenting and reporting mechanisms) to strengthen their preparedness and response capabilities.

Lastly, an effective BIA process relies on appropriate planning and scoping. The BIA or similar information-gathering exercise would help improve understanding of all factors impacting how to plan and respond to a disruptive event.

Q 17  What are the most common approaches to executing a continuity risk assessment?

The fundamentals of a continuity risk assessment do not differ from other risk assessments. Continuity risk should be evaluated from the standpoints of probability, impact, and mitigating and compensating controls, just like any other type of risk. From a probability standpoint, organizations should:

- Consider their unique risk profile. For instance, organizations located in an earthquake zone will devote more planning to the response and recovery from a possible earthquake event.

- Conduct research to determine the probability of a threat and focus the assessment on threats most significant to the business. Most organizations have cybersecurity risk and aspects of geographical hazards such as earthquakes, hurricanes and tornadoes. Additional risks may be specific to the organization’s industry, such as supply chain, seasonality and compliance nuances. Continuity risk assessments should consider a number of factors, as types of events may evolve over time.
When assessing impact, organizations should:

- Determine the type of impacts that may arise from any event. The collective impact from an event should be considered carefully. Impacts can take multiple forms, such as operational or technological, financial, and reputational, as well as legal, regulatory and compliance related.

- Categorize the risks (or events) that have similar attributes. Events that cause broad operational, reputational and compliance risk would warrant more attention than events that are localized or isolated and unlikely to cause detrimental impacts.

Business continuity planners should consider available controls as countermeasures or mitigation techniques for the most probable and impactful of the risks. These techniques may include enhancing environmental or physical security controls or documenting a scenario-specific incident response plan for that specific risk (e.g., a hurricane preparedness plan for the Gulf Coast or an earthquake response plan for the West Coast).

**Q 18** What are some alternatives to performing an exhaustive BIA and risk assessment?

When planning for near-term events with business continuity implications, organizations are increasingly implementing creative processes to streamline the rigorous and detailed analysis effort required to complete a formal BIA and risk assessment, which can span many months. Organizations often do not have the time to complete an exhaustive analysis of all environmental, man-made, business process, supply chain and IT continuity risks.

One option to identify risks and prioritize recovery needs is to perform an abbreviated BIA and/or risk assessment through an executive work session. A facilitator leads a high-level cross-functional team to define impacts (at an organizational level, as opposed to a business-function or technology level), which in turn will be used to assist with establishing business-process and technology priority levels, recovery objectives and an order of recovery. This process is designed to reach preliminary conclusions in days, as opposed to many weeks, using the input of business leaders throughout the organization.

With regard to an alternative for the comprehensive continuity risk assessment, a business continuity steering committee and/or project team can define a realistic worst-case scenario to inform an abbreviated scoping and planning process. The scenario, which should impact the entire organization, can provide a framework to assist planners with developing response and recovery strategies. The value in this approach is found in the streamlined manner of identifying the numerous impacts of a disruption without dissecting each type of triggering event. Many organizations have found that using a worst-case scenario can help them plan for less-impactful events.

While substituting a risk assessment and BIA process with an abbreviated approach will not result in a thorough understanding of all risks and impacts to the organization, the examples noted provide a way to jump-start the planning process, particularly when the organization faces a distinct deadline or management has not formally endorsed the BCM process. Going forward, the abbreviated processes should be refreshed with more thorough analyses that consider information and perspectives from multiple levels within the organization.
Are there ways to make the BCM planning process more efficient and effective?

The focus of any continuity planning effort should address the most relevant threats identified during the continuity risk assessment and consider impacts identified through the BIA. Not every area of the business needs to be prepared for every type of event or have the same level of rigor applied to continuity planning. Companies should consider being more thorough on their most critical business lines and apply a lighter touch (e.g., less frequent, or less rigorous maintenance or testing) for less critical areas of the business. Ensuring alignment of the recovery priorities and subsequent plans will enable a more efficient response and effective recovery. The business continuity plan should address the facilities and resources necessary to enable effective business continuity operations.

A common approach for recovery planning is focusing on extreme but plausible (i.e., worst-case) scenarios. Plans based on extreme but plausible events should also allow for flexibility in their implementation to allow for use during less-impactful situations. Alternatively, organizations may choose to mitigate likely scenarios by implementing a scenario-specific incident response plan (IRP) that aligns with risks associated with events that may be highly likely and highly impactful. Examples of these events include hurricanes along the Gulf Coast, earthquakes along the West Coast, or tornados in Tornado Alley. In these instances, the existence of plans that were developed for a likely event improves awareness of what to do, can lessen the risk of harm or severe injury, and can be worth any upfront cost associated with planning or training.

Consideration may also be given to using checklists and flowcharts to summarize response and recovery procedures, as opposed to more robust narratives. If the necessary steps are clear, the likelihood that those steps will be followed is higher. The use of checklists and flowcharts may also shorten any review and revision cycles needed as part of program management, as the amount of editing and formatting will be reduced.

Lastly, it is recommended that tests (or exercises) of the teams are used as opportunities to “break the plan.” A focus on continuous improvement should allow the program to progress as areas for improvement are captured. Companies should consider a thorough approach for critical business lines and processes that include end-to-end testing and apply a less rigorous testing approach to those business lines or processes that are considered less critical or nonessential.

To improve resilience in the post-pandemic period, organizations should learn from both the successes and failures of their pandemic crisis management. Firms that did things particularly well should not be complacent — for one, no one is completely out of the woods just yet.

— Ron Lefferts, Managing Director, Global Leader of Technology Consulting
Q20 What is the difference between crisis management and crisis communications?

Crisis management is an entity’s overall effort to stabilize and prevent further damage after an unplanned event. Crisis management takes place at all organizational levels, beginning with executive management. It includes initial efforts from all departments, such as communications and public relations; regulatory affairs; environment, health and safety (EHS); human resources; legal; corporate security; and all business units.

Crisis communications is a crucial component of crisis management. It encompasses all communications before, during and after an event, including targeted communications to employees, customers, community, regulatory agencies, shareholders, the board of directors and all others who may be affected by the situation. These communications can be deployed during any type of event that may be deemed a crisis, from a product recall to a data center fire. The trend in crisis communications is to have multidisciplinary teams for internal and external communications working together on messaging. Public relations, sales and marketing, communications, legal, human resources and investor relations may collaborate to develop and deliver internally and externally directed messages.

This example illustrates how crisis management and crisis communications can work together:

After a manufacturing director is confirmed to have been infected with COVID-19, EHS notifies the crisis management team that the director’s temperature was on the rise throughout the week but there was no concern about the virus until additional symptoms surfaced. The director oversees two manufacturing plants and is consistently in the corporate office for meetings. EHS informs the crisis management team that the director was on-site at all three locations throughout the week. The crisis management core team makes the following decisions:

- The CEO decides to close both factories and the corporate office until further notice.
- General counsel advises the CEO to require testing for all employees before reopening the facilities.
- The CFO determines that the organization should pay employees regardless of the shutdown.
- The CRO notes the various regulatory implications that could result from the outbreak.

The crisis communications team takes the next step to communicate all decisions internally to employees and to release a statement to external stakeholders (customers, shareholders and regulatory bodies).

As shown in this example, crisis communications processes are dependent on decisions made by the crisis management team, which acts as a liaison between the business and internal and external stakeholders.
If an organization uses social media channels to communicate with its customers, clients and other key stakeholders in the course of normal business activities, those channels should be integrated into its crisis communications strategy. If an organization does not use social media during normal operations, a crisis event is the wrong time to start.

While it can be a very valuable tool, the use of social media involves considerable risks. Certain information should not be shared on social media due to the potential for sensitivity and compliance risks. When engaging with the public over any social media platform, there are reputational risks that also need to be considered.

In a crisis situation, effective social media communication requires a higher level of care and management than during normal operations. Organizations should have a set of instructions prepared in advance for how social media will be managed during a crisis, with consideration given to publishing approvals and content authorizations, compliance matters and reputation management. Those instructions should include using a more rigorous social media control structure for the duration of the crisis. The control structure should provide employee guidance and reminders on how individuals should use social media during crises. Social media policies should state clearly — during a crisis and at any other time — which individuals and, by extension, shared accounts are authorized to speak for the business.

Among its advantages, social media offers employees an opportunity to connect and network as part of various subgroups, a dynamic that can promote ad hoc connections, especially during a crisis. Employees can also assist each other, using social media, in recovery of a business or even to recover personally from an event. While only semi-sponsored from a business standpoint, these channels can be well-received and efficiently "tagged" by the company’s official social media accounts to raise awareness and share information to a wider audience.

Technology is a primary tool for enhancing organizational resilience. Software as a service (SaaS). Remote desktops. Public cloud providers. Internet of things (IoT). These technologies have had a significant impact on the ability of an organization to withstand adverse events by, among other things, enabling the decoupling from a desktop, decreasing concentration risk, and providing enhancements in the storage and availability of data.

— Kim Bozzella, Managing Director, Protiviti
Do you need a business continuity management software/system (BCMS) to develop an effective BCM program?

Not necessarily. For organizations that are building an enterprise BCM program from scratch, buying BCM software is not the recommended first step. A software’s structured nature can force users into providing generic responses to crucial discovery questions and important planning phases where some level of variance can be valuable. Another hazard with BCM software is the false sense of security it may provide teams that rely solely on it.

Organizations that do not have concerns related to regulation or complexity can run an effective BCM program with office productivity software paired with a knowledge management application that may already be in place and familiar to the employee base. However, BCM software can be valuable for:

• Highly regulated businesses like financial services or insurance providers. There, a centralized BCM application and plan repository may simplify adherence to compliance obligations.

• Enterprises that have multiple processes, many international locations, varying jurisdictions, or diverse geographical threats. Such organizations will likely benefit from using a centralized BCM software to manage the complexity of their BCM programs.

For organizations that use BCM software, it is important to remember the application is a means to an end. BCM software does not guarantee an effective BCM program or a cohesive and effective response.

Lastly, businesses should treat the BCM software acquisition as they would any other application: analyze business requirements to guide a diligent application selection process, include the system in the company’s third-party risk management (or vendor management); process and budget for additional headcount to support and maintain the system and data post-implementation.

One way an organization can improve its continuity impact assessment process is by taking a scenario-agnostic approach and focusing on the disruption-event impact on critical business processes, key personnel and supporting technology. Establishing a repeatable process that focuses on the impact vs. the cause of the disruption will help you identify, track and manage these risks on an ongoing basis, and will serve as the foundation for well-constructed response plans.

— Matthew Watson, Managing Director, Protiviti
Q23 What are some of the key considerations when developing Information Technology Disaster Recovery (ITDR) strategies?

The first consideration when developing a comprehensive set of ITDR strategies is to ensure they are aligned with the organization’s business continuity requirements. It is not uncommon for IT teams to drive priorities while inadvertently being misaligned with the business needs.

Next, the impact on customers when systems fail is important and should be considered. For instance, depending on the organization, customers may tolerate disruption to or unavailability of services for some time. In other cases, customers may take their business to competitors without notice. Teams should consider the cost of a lost sale and how committed the customer is to the relationship (e.g., airline customers can easily take their business to a competitor, but a financial services client would face a more onerous task of switching to a competitor).

Further, teams should consider the respective industry regulations and ensure the ITDR plan complies. It is not unusual for one instance of noncompliance to intensify the scrutiny of regulators overall. Moreover, any instance of noncompliance puts a brand’s reputation at risk.

Another consideration is cost versus benefit. ITDR strategies should always weigh the degree of resilience against the cost to achieve it. A complete, immediately available backup of every system is ideal, but might not be feasible from a cost perspective.

The role of third parties in the organization’s supply chain and their operational resilience from a technical perspective is also valuable. Teams should understand what recovery capabilities are stipulated in formal agreements and confirm that vendors can keep those commitments.

Additionally, teams need to consider the volume, latency and sensitivity of data consumed and processed by each system. These factors guide decisions about the location of technical recovery capabilities and how current the data needs to be when it is recovered. If the ITDR strategy includes co-location facilities, it is prudent to consider data volume versus available bandwidth and the speed with which data must be restored.

The baseline hardware requirements of each system are important. One common mistake is to use decommissioned equipment for backup. Often, as systems are updated and their usage and data sets grow, these older platforms become inadequate.

Lastly, consider the skill sets of the technologists on tap for recovery, focusing on whether they are equipped to resume operations as rapidly as the business needs.

Q24 What should disaster recovery planners consider when choosing primary and alternate sites?

In the past, BCM practitioners had a rule of thumb to have primary and alternate sites at least 30 miles apart. These days, decisions about siting are more likely to depend on an organization’s risks and the nature of its systems and data. Given the current low cost of bandwidth and the availability of multiple viable options, organizations have more latitude in selecting primary and alternate sites. Still, the following factors should be considered when making siting decisions:

- A system’s function should drive requirements for backup location. For trading systems, for instance, the transaction speed and data volume would require high-performance network connectivity between sites. Other systems may be less demanding.
- Businesses should be prepared to move systems to alternate sites if the primary location is exposed to disasters such as a flood, earthquake or hurricane. A single event could impact a wide geographic area of potentially hundreds of miles. If this is likely or an unacceptable risk, then the alternate site should be outside the risk area. Likewise, risks such as terrorism, geopolitical instability and unstable infrastructure in a particular region could have a significant impact on a data center.
Regulators may specify requirements for siting data centers, disaster recovery sites, alternate offices and business resumption centers. Some requirements may be relaxed if regulators can be assured that the business has comprehensively assessed and documented its own risks and demonstrated diligence by refreshing its plans and assessments regularly.

Location of staff has historically been a major consideration in siting primary and alternate data centers, but it is less important more recently. The COVID-19 pandemic has shown that businesses may not need staff located near alternate sites. The staff's ability to access facilities in extreme weather is constrained if co-location is part of the disaster recovery strategy.

If a business' systems interact with the public via the internet, alternate sites need bandwidth equivalent to the primary site, so failover is transparent to the user. Bandwidth is an even more significant factor when backups are not updated in real time; recovery in these situations involves transferring large volumes of data swiftly.

Cloud computing provides an attractive alternative to owned and operated data centers, or even hosted data centers. Cloud providers often concentrate multiple data centers within a region, enabling them to respond effectively to localized issues. These concentrations may be repeated in other regions to create an exceptionally resilient network that is responsive to failures at any single location.

Data replication strategies can also impact the desired distance between primary and alternate sites. Synchronous replication might be safe for an application's most critical data, while less critical data could be replicated asynchronously.

Q 25  **How is advancement of technology changing disaster recovery planning considerations?**

The availability of robust, secure cloud solutions for disaster recovery represents a fundamental shift in disaster recovery planning. Cloud solutions can be more secure and provide better failover capabilities than businesses can accommodate with their on-prem environments.

For organizations that employ cloud technology for their production environments, resiliency and recovery are intrinsic to the platform, and disaster recovery (DR) capabilities are easily added. It is essential for these organizations to possess the expertise to govern and manage cloud implementations, keeping requirements of business process owners in the forefront. When businesses attend to these concerns, configuration of DR features in the cloud is reasonably straightforward.

There are businesses that cannot consider cloud solutions for disaster recovery. Disaster Recovery as a Service (DRaaS) is another way for such businesses to offload risks associated with hosting and operating their own data centers, and they can usually do so at a lower cost.

Whether a business pursues an on-premises or cloud-based DR solution, testing the chosen platform is critical to demonstrating that failover and related processes are designed, documented and executed as expected. Organizations taking advantage of DevOps practices already benefit from an automated approach to developing, building, testing, and configuring and deploying software. DevOps also provides a high degree of confidence that systems will run effectively in any environment to which they are deployed. Businesses that do not follow DevOps practices will want to pay greater attention and carefully manage risk related to design, development and deployment of systems that grow organically or ad hoc, or that are deployed via manual processes.

It is also worth noting that edge technology is growing in popularity in the context of DR planning. Where high availability is important, organizations push systems and content to providers all around the world. This approach limits the risk of overloading a central data center. Data can be stored and processes run at these remote points, providing an extra level of resilience for highly available systems and services.
Q 26  What are some key considerations for pursuing Disaster Recovery as a Service (DRaaS) or other disaster recovery vendor solutions?

There are many solutions for setting up internally owned and managed disaster recovery capabilities or engaging with third parties at varying levels — from specific services/parts of the solution to entirely out-of-the-box solutions fully managed by an outside firm.

Disaster Recovery as a Service (DRaaS) provides a way for businesses to offload risks associated with hosting and operating their own data centers, usually at a lower cost.

Well-documented, clear requirements are essential to managing DRaaS costs. Detailed requirements should correspond to line items comprising the overall price, which may build in an added level of rigor and discipline to DR planning to some organizations.

DRaaS works most effectively for common technologies that vendors can easily operate and manage. When systems are customized or tightly integrated with other elements in the technical environment, they are more challenging for the vendor to support. DR teams should also consider whether the production environment is using old, unusual or highly specialized equipment, and should integrate the appropriate level of due diligence when finding vendors who have that same equipment available. For cases like these, businesses still have the option to engage providers who address data recovery, while retaining responsibility for infrastructure recovery in-house. However, infrastructure recovery can also be supported by vendors. Here, the challenge is to ensure that the system runs as well on the vendor’s platform as it does in the business’s production environment.

When choosing DRaaS, data recovery and infrastructure recovery solutions, a business needs to examine its requirements in the context of cost versus time to recover. Traditional cold sites have equipment standing ready to be configured and updated when they are needed. Warm sites have servers ready for installation of production environments. Hot sites are set up for immediate use, with up-to-date systems and data ready for failover.

With the variety of offerings for ITDR support in the market now, businesses have more options than ever. The key to success is knowing requirements, documenting them in a detailed way and seeking the vendors whose capabilities best match the needs of the business.

Q 27  How can organizations leverage cloud services as a viable disaster recovery solution?

Cloud-based solution providers offer a vast array of options, so businesses can allow their own disaster recovery (DR) strategies to drive their selections. Start with an assessment of the business’s own capabilities versus the resilience it needs. Consider size, budget and maturity level of the organization, as well as DR requirements particular to the business.

For organizations whose DR strategy is already sound, implementation of cloud-based solutions can be straightforward and rapid. Among the multitude of options, cloud-based DR solutions fall into two fundamental categories:

- High availability and hot-hot resilient services, where a business’ servers and data are replicated from the primary to the secondary data center with the shortest possible recovery time. This approach takes advantage of cloud-native features and offers configuration options so businesses can establish their own resilience parameters. To duplicate these capabilities without cloud-based services, a business would need three or more instances of its production infrastructure, located in various regions, each with staff on site. In these terms, the value of cloud-native architecture for DR is clear.

- Data recovery and backup, whereby businesses can back up their data to the cloud over an Internet or direct network connection. This solution relieves businesses of the responsibility for managing various forms of media as well as the data backup and recovery storage infrastructure, but they’ll remain responsible...
for restoring the backed-up data to infrastructure in the event of an outage. Therefore, cloud-based data backup only partially meets DR requirements for most businesses. Cloud providers who only offer data recovery and backup are beginning to lose ground against competing cloud providers who offer more robust, high-availability solutions, raising questions about the long-term viability of a data-only approach.

Q28  How does switching to a cloud-based disaster recovery solution affect risk in the organization?

While a cloud-based disaster recovery (DR) solution introduces the risk associated with storing data outside the organization, that risk is offset by the resilience gained by adopting a cloud-based approach to DR. Cloud providers invest significant resources into security measures, both in the latest security technologies and in the skills of their personnel. Adopting a cloud-based approach to DR could increase an organization’s risk tolerance from a variety of perspectives. Organizations that adopt cloud-based DR can benefit in the following ways:

- The cost of DR testing in the cloud is usually lower than it is for organizations with owned or hosted data centers, increasing the organization’s appetite for more frequent tests. More frequent tests result in more resilient environments.
- Cloud-based DR environments can be set up on demand, so the organization is freed from hardware procurement processes (including selection, negotiation, ordering, installation, configuration and provisioning), as well as procurement costs and delays. This vastly increases the flexibility of DR environments, facilitating nimble modification of systems.
- Cloud-based DR environments provide resilience faster and at a lower cost, so organizations can launch new products without compromising the DR strategies. This enables businesses to meet regulation-driven resiliency requirements with little additional overhead.

Ultimately, organizations incur the risk of storing data outside the organization in exchange for superior resilience, greater flexibility and lower risk overall. Organizations are unique in their security needs and regulatory requirements and should evaluate cloud-based DR’s advantages from the perspective of these factors.

Q29  What approaches are available when leveraging a cloud solution for disaster recovery?

The approach any organization takes to leveraging a cloud-based disaster recovery (DR) solution will depend on the organization’s rate of adoption of the cloud strategy. Organizations that already host applications on cloud platforms will want to take advantage of the built-in features their cloud providers offer.

Organizations not yet in the cloud may want to offload responsibility for operating their own disaster recovery data centers and instead turn to cloud providers that specialize in services like these, with approaches varying from full-scale to point solutions. It is not uncommon for organizations to embrace the cloud version of the application, as resilience is often a benefit associated with a move away from an on-prem strategy. If a vendor offers a cloud-based service for their application, it is possible to run the system with the cloud version of the application as a backup.

Approaches to adopting cloud-based DR vary by degree of reliance on integration with cloud technology. In other words, solution options vary by the degree to which an organization chooses to take advantage of cloud technology’s intrinsic benefits. To take greatest advantage of these features requires fundamental changes to the organization’s system architecture.

Approaches can be broadly considered by increasing degrees of cloud integration:

- Cloud-based DR as an additional data center requires configuring a cloud environment to emulate the on-premise...
data center. This approach replicates servers, processes and all other components of the physical environment to enable swift and smooth transition when needed. Organizations can specify that the cloud environment be set up in advance. This approach of treating the cloud as another data center and preconfiguring it is more sophisticated and complex than many organizations require, but it can represent dramatic cost savings for some applications and some use cases.

Cloud-based DR takes advantage of cloud-native offerings, including snapshots, data replication and other services. Cloud-native applications are built with a high degree of automation and resilience in mind. Cloud-native applications are designed to be more resilient, as failover can be instant and transparent for the best-available resilience of systems. In comparison, applications designed for DR in a traditional data center are typically reliant on manual monitoring and recovery activities.

Q30 What are some key considerations for selecting and/or negotiating hosted solutions or disaster recovery support?

Selection of a disaster recovery (DR) solution depends primarily on an organization's specific technical recovery needs. Cloud-based DR providers offer superior capabilities and security, but it is unusual for a cloud provider to negotiate anything at variance with their standard service level agreements (SLAs). In many cases, organizations that use unusual or older infrastructure may find cloud providers do not offer customized solutions that allow for a company's architectures or nuances. In these instances, these companies must rely on traditional DR providers that are constrained by the physical hardware in their data centers. Organizations can also engage a third party to manage their cloud-based DR, placing the third party between themselves and the provider to bolster the SLA with additional services. When selecting cloud-based DR providers, companies should ensure the provider can scale to accommodate the organization's needs and, if so, understand how, and how quickly, that scaling is accomplished.

Whether they choose cloud-based or traditional DR providers, companies should ask the following:

- How long can the organization run in DR mode? Standard contracts may specify a week or two. Organizations should consider whether that duration is enough and must understand the implications if that timeline is exceeded.
- Can the provider assist with failback (i.e., restoring data saved or modified in DR mode back to the primary environment)?
- How is DR testing conducted, and how does the provider support those tests?
- How is the provider's technology and physical space used when the organization does not need it? Do the provider's facilities function as primary for one customer and secondary for another, for example?
- How does the provider handle events that require simultaneous recovery of multiple systems? If the provider has several clients in a DR situation at the same time, how are they prepared to address that circumstance? To what extent can the provider abide by the SLA in extreme circumstances or when the organization may be competing with the provider's other customers for the same resources after a large-scale or regional disaster?
- Is the hot site also used as a primary site for other clients, thereby calling into question whether it is always available? Sites used only for DR — and thus unused for periods of time — may not function as planned when needed.
- Can the provider (or the organization's own team) configure infrastructure remotely? In the absence of this capability, DR infrastructure can "drift," causing a misalignment with the production environment.
- Does the provider stay current with new versions of hardware, operating systems, middleware and other infrastructure components?
What are the costs related to testing and other processes to exercise the infrastructure from time to time? These are sometimes overlooked in negotiations, but they do require time and resources on the part of both providers and their customers.

Ultimately, when choosing cloud-based or traditional DR providers, it is important to be clear and detailed about delineating responsibilities.

**Q 31 What other requirements and recommendations should organizations consider as part of their IT governance practices?**

There are numerous BCM-related resources that may offer guidance, requirements and/or recommendations which apply to most companies. For instance, most of the well-known cybersecurity standards (e.g., NIST CSF, ISO 27001, CIS CSC) focus not only on the confidentiality and integrity of data but also its availability. Additionally, the increased focus on privacy with the introduction of the General Data Protection Regulation (GDPR) and the California Consumer Privacy Act (CCPA) has heightened the focus on not only how to maintain continuous access to data subject information but also how to ensure privacy protections regardless of how or where the data is stored.

The expectations on IT leadership of both public and private sector organizations for improved preparedness are higher than ever before. Additional government and industry bodies and/or requirements and control standards for technology components of business continuity and crisis management are listed in the regulatory sources in the Appendix.

“

A vital but frequently overlooked component of a business continuity program is a cybersecurity incident response plan. During times of crisis, organizations are under strain and may inadvertently let their guard down. It’s vital to have a plan in place to respond to and recover from cyber incidents such as data breaches, phishing attempts or DDoS attacks that can occur during or independent from major disruptions. More importantly, that plan should be regularly tested to uncover any flaws or constraints in process and technology.

— Curt Dalton, Managing Director, Protiviti”
THIRD-PARTY RISK MANAGEMENT AND BCM
Q 32  How do sourcing, outsourcing and procurement strategies impact business continuity and operational resilience?

An organization’s approach to sourcing, outsourcing and procurement has a direct impact on its ability to maintain business continuity. If the sourcing and procurement strategy focuses exclusively on driving down costs, organizations may find themselves sourcing from fewer providers to leverage spend and increase buying power. Relying on fewer vendors increases the risk, however, should any one vendor be unable to support their customers due to a disruption and an inability to recover promptly. Organizations should consider all aspects of a vendor’s capabilities and total cost of ownership, including business continuity, and not consider cost alone when selecting vendors.

Organizations in heavily regulated industries must understand specific requirements and obligations as they pertain to third-party management, including requirements for business continuity management and disaster recovery capabilities and plans. These considerations, including risk assessment, due diligence, contracting requirements and ongoing monitoring, must be addressed as part of the sourcing and vendor selection process.

Outsourcing is especially impactful on an organization’s business continuity capabilities. Executives sometimes develop blind spots when they assume that outsourced providers are managing their own business continuity effectively and when estimating the impact that outsourced provider operations and processes can have on their own internal processes. As a result, organizations do not typically apply the same level of rigor and oversight to outsourced functions as they would to internal functions. The inclination to assume outsourced vendors are managing business continuity effectively grows more hazardous as organizations increasingly rely on outsourcing. It is prudent for organizations to understand contingencies that may need to be employed as they relate to any third party deemed critical.

Q 33  How should organizations identify and prioritize vendors to manage business continuity effectively?

Ideally, all new and prospective vendors go through a risk assessment process that addresses the inherent risks across applicable risk domains (including business continuity) associated with the service or category of spend being addressed. The results of the initial risk assessment, combined with vendor criticality — as identified through the business impact analysis (BIA) — should dictate the level of due diligence required, with results of the due diligence culminating in segmentation and tiering. The vendor segmentation should then drive contract considerations and specific requirements, as well as frequency of ongoing monitoring. Segmentation and tiering will dictate whether, and how often, the organization reviews and tests vendors’ business continuity plans. The riskiest or most critical vendors might be reviewed every quarter, where the least risky or least critical vendors may be reviewed only every year or two.

When considering management of vendor relationships, organizations can prioritize based on the difference between transactional dealings with vendors of commodity goods and services that can be readily replaced, versus more strategic relationships, where the cost, time frame and complexity of switching providers is more severe. These more strategic vendors should be prioritized and more actively managed as part of an organization’s overall business continuity posture. Organizations should assess if their strategic vendors’ business continuity plans are aligned with the organization’s own strategy and should evaluate how these vendors manage their plans in terms of oversight, testing and other factors.
For vendors that supply goods — particularly goods that contribute to an organization’s finished product — businesses should assess the revenue generated from the finished product to determine the criticality of the vendor’s goods to production and prioritize accordingly.

For information technology vendors, considerations should include whether the vendor will access the organization’s network or share data, what software is used to perform tasks on the network, how many business users rely on the vendor-provided service, and what business process the service supports. The vendor’s responses may trigger more questions to understand the vendor’s systems and protocols better. How is the application developed and hosted? Do they test the application regularly? Does the vendor have practices in place to recover systems quickly enough?

Q 34  Why is it important for organizations to understand and assess their vendors’ business continuity plans and capabilities?

Organizations can enhance their in-house recovery strategies if they have a better understanding of their vendor’s contingency plans. Having a high level of comfort in a vendor’s plans and how those plans are validated and tested means the company may not need to put as much time and resources into a particular element of planning. Also, knowing how those critical vendors will respond to a disruption can influence the organization’s recovery activities.

The criticality of any good or service, and the probability and impact of vendor outages and disruptions, are likely considered as part of the organization’s BIA, where each vendor is assigned a level of criticality and, perhaps, a recovery time objective (RTO).

Business continuity procedures should include documenting whether a vendor possesses or will gain the capabilities to ensure they can provide goods and services within agreed-to SLAs. Additionally, as vendors are onboarded, they may be segmented and tiered according to the inherent risks, to govern the depth and extent to which any vendor’s business continuity capabilities will be overseen and reviewed.

Q 35  How should a business continuity program consider the impacts of disruption to vendor or supply chain partner operations?

An organization’s business continuity plan should document its vendors’ or trading partners’ abilities to identify, respond to and recover from potential business interruptions. The process starts with identifying what potential risks could lead to an interruption of services delivered to consumers or disruption of the entire supply chain. The process must consider all components and contributors to the consumer service or to the supply chain.

Business continuity planning typically assesses probability and impact of any threat. It is important, however, to consider unlikely threats as well. These are sometimes called black swan events — unexpected outlier events with severe consequences that are extremely difficult to predict. Defining and testing risk response strategies in anticipation of both likely and unlikely events protects organizations from undue struggle and chaos when a crisis is underway; they would only need to execute on the plans already developed.
Should vendors’ business continuity plans and capabilities be tested? If so, how often?

When an organization tests its business continuity plan, either as a tabletop exercise or a thorough dry run, the vendors supplying critical goods and services should participate. Vendors with roles in the organization’s disaster recovery strategy should collaborate on periodic cutover testing.

Assessments of vendors should include evidence that they have sound business continuity programs and that those programs include rigorous testing, followed by a review of test results to demonstrate that the vendor can meet the organization’s recovery time objectives.

Where a vendor’s outage could have high impact on the organization, such tests might occur as frequently as annually. Where vendor relationships carry less risk, testing might be conducted in alternate years.

In the financial services industry, financial institutions are more focused than ever on operational resilience, of which business continuity is a key component. The highly interconnected nature of banking environments creates significant concerns about the ability of a contagion to disrupt banking services. Similar concerns are emerging in other industries, underscoring the need for a continuing focus on business continuity and resilience.

— Ali Yasin, Managing Director, Protiviti
REGULATIONS, STANDARDS AND GUIDANCE
Q 37  How should regulations and standards shape the development of a BCM program?

BCM regulatory requirements and standards are increasingly being enhanced in response to a growing focus on corporate governance and risk management and the devastating impacts of technology disruptions and catastrophic events. The enhancements are designed to help organizations develop more effective continuity responses to the evolving threat landscape, including providing enhanced protections for employees and all those who depend on an organization’s services (e.g., customers, clients and patients).

Regulations and standards are used to support BCM program development, measure adherence and assess maturity. While regulations and standards often provide guidance on required or suggested areas of focus and approaches to BCM, they rarely dictate specific items, formats or levels of detail in planning documentation. The most comprehensive guidelines and standards are geared toward financial services. Using these more rigorous guidelines, it is not uncommon for other industries to apply the relevant controls and strategies as they model all best practices.

Q 38  What specific guidance does the Federal Financial Institutions Examination Council (FFIEC) provide regarding BCM?

The FFIEC standard is recognized as one of the most aggressive BCM standards in the U.S. marketplace. It places significant emphasis on governance, risk assessment, BIA, planning, recovery, resiliency, testing and maintenance requirements. It also contains a section related to senior management’s business continuity responsibilities, which is a helpful reference for any company.

Many organizations, including non-financial services entities, model their BCM programs after the FFIEC standard. Originally published in 1996, the standard was significantly expanded in 2003, 2008 and 2015, and most recently refreshed in November 2019. Although still listed in the category of IT examination, the FFIEC standard states that BCM should be based on “enterprisewide, process-oriented approaches that consider technology, business operations, testing and communication strategies critical to the continuity of the entire entity.”

Additionally, the 2019 update changed the booklet title from “Business Continuity Planning” to “Business Continuity Management.” The update reflects the changes in customer and industry expectations for the resiliency of operations. Further, the booklet emphasizes that “business continuity should not be focused only on the planning process to recover operations after an event, but rather it should include the continued maintenance of systems and controls for the resilience of operations.

Business continuity should be incorporated into the risk management life cycle of all systems, processes and operations of an entity.”

The points below summarize the FFIEC guidance regarding developing the scope of an effective and efficient BCM program and establishing a repeatable life cycle:

- Effective BCM governance depends upon the involvement of the board and senior management.
- BCM elements should align with strategic goals and objectives.
- A thorough BIA and risk assessment should form the foundation of a comprehensive BCM program.
- A BCM program should include strategies that meet both recovery and resiliency objectives.
- The BCM program should be developed on an enterprisewide basis, and should incorporate incident response, disaster recovery, business resumption and crisis/emergency management.
- A BCM training program should be implemented for personnel and other stakeholders.
- The effectiveness of the BCM program should be validated through annual, or more frequent, testing.
The BCM and test program should be thoroughly documented, evaluated by institution management, independently reviewed by an internal and/or external audit function, and reported to the board.

The BCM and test program should be updated to reflect and respond to changes in the institution and gaps identified during continuity testing.

Other financial institution policies, standards and processes should be integrated into the BCM program.

Rather than stipulate a series of “do’s and don’ts” with explicit requirements, the FFIEC booklet provides companies with practices to make robust assessments of their needs and reasonable judgments on the composition and content of their BCM programs. For example, following their discussion of institutions serving critical financial markets, the FFIEC suggests that the BCM program and its critical elements be based on an entity’s size and complexity and aligned with the financial institution’s business strategy and risk appetite.

Q 39 What are ISO 22301 and ISO 22313?

ISO 22301, published by the International Organization for Standardization (ISO) in 2012 and updated in October 2019, established an international standard that provides the structure and requirements for implementing and maintaining a BCM program. As with other ISO standards, ISO 22301 applies the Plan-Do-Check-Act (PDCA) model and focuses on the business continuity life cycle. Organizations seeking ISO certification of their BCM program can do so by engaging an accredited third-party certification group. The ability to certify a BCM program and provide a degree of assurance to third parties (e.g., customers, clients, partners, regulatory bodies) with respect to the integrity of the program is an attractive proposition for a number of organizations.

The introduction of ISO 22301 essentially replaced BS 25999-2, which was developed by the British Standards Institution (BSI). In fact, ISO 22301 is an upgrade because it places greater emphasis on understanding requirements, setting objectives and measuring performance. Ultimately, organizations that have previously aligned their programs with the BSI standard should have a straightforward transition to ISO 22301.

ISO 22301 was designed to be applicable to all types of organizations. The principles are familiar to seasoned BCM professionals, but how the requirements are ultimately applied depends on the risk environment in which the organization operates and management’s goals and objectives.

ISO 22313, published in 2020, clarifies the concepts introduced by ISO 22301 with explanations and examples to assist organizations during implementation. While ISO 22313 does not introduce any new concepts or requirements, it provides a better sense of what an ISO 22301 BCM program looks like and how the standard can be applied.

Q 40 How does NFPA 1600 differ from more familiar BCM guidance?

NFPA 1600 is a standard published by the National Fire Protection Association (NFPA) that focuses on disaster management and business continuity. Headquartered in Massachusetts, NFPA is a standards-making body known for its NFPA 101®: Life Safety Code®, which governs most life-safety issues in commercial buildings across the country. It is common for local and state governments to adopt NFPA standards verbatim into their building and life safety codes. The standard became especially significant after the federal 9/11 Commission recommended it as the National Preparedness Standard and encouraged entities such as insurance companies and credit rating agencies to include it in their evaluations of customers. The U.S. Department of Homeland Security (DHS) sponsors a resource known as “Ready Business” and has adopted NFPA 1600 as the American National Standard for developing a preparedness program.

Work on the NFPA 1600 standard began in the 1990s, with the first version published in 1995 and most recently updated in 2019. Unlike other standards and regulatory
requirements, NFPA 1600 is industry neutral and even applies to the public sector. When it was first published, NFPA 1600 was three pages long and included elements of prevention, preparedness, response and recovery. Today, NFPA 1600 is a complete emergency management and business continuity standard that includes guidance on crisis communications, emergency operations center (EOC) management and family preparedness.

There is no specific industry or class of organization that is legally required to adopt NFPA 1600. However, many organizations use it to guide the development of their continuity and emergency response preparations. The standard is sufficiently flexible and can be adopted by all types of organizations (e.g., large, small, public or private), as it is structured on general recovery principles that would be found in an effective emergency management program (e.g., BIAs, crisis management, plan development, testing, training and education). Organizations can tailor the standard to their needs and build procedures specific to their recovery needs. The 2019 edition focuses on crisis management in general and crisis communications in particular, consistent with the distributed nature of the current workforce and the need to effectively communicate with both employees and external groups.

Q 41 How does the COBIT standard address BCM?

Control Objectives for Information and Related Technologies (COBIT) is a generally applicable and accepted standard for sound IT governance and management practices. The standard provides a reference framework for management and users, as well as for information systems (IS) audit and control and security practitioners. COBIT, issued by the ISACA and now in its sixth edition (COBIT 2019), provides tools to assess and measure an enterprise’s IT capability across one governance and four management domains:

- Domain 1: Evaluate, Direct and Monitor (EDM)
- Domain 2: Align, Plan and Organize (APO)
- Domain 3: Build, Acquire and Implement (BAI)
- Domain 4: Deliver, Service and Support (DSS)
- Domain 5: Monitor, Evaluate and Assess (MEA)

Business continuity activities are addressed primarily in the DSS04 domain/process area. The “manage continuity” process, as described by COBIT, is designed to “establish and maintain a plan to enable the business and IT organizations to respond to incidents and quickly adapt to disruptions.” This process enables continued operations of critical business processes and required information and technology services, and helps firms maintain available resources, assets and information at a level that is acceptable to the enterprise.

Although COBIT tends to be IT focused in many process areas, the “manage continuity” process incorporates characteristics that include IT as well as business recovery activities. The DSS04 process is organized into eight practices:

- Define the business continuity policy, objectives and scope
- Maintain business resilience
- Develop and implement a business continuity response
- Exercise, test and review the business continuity plan (BCP) and disaster response plan (DRP)
- Review, maintain and improve the continuity plans
- Conduct continuity plan training
- Manage backup arrangements
- Conduct post-resumption review

Each practice is supported with suggested activities, example metrics, references (e.g., National Institute of Standards and Technology (NIST) 800-53), typical organizational responsibilities, process inputs/outputs, recommended skills and corresponding policies.
Describe the connection (if any) between the Sarbanes-Oxley Act (SOX) and business continuity.

When the Sarbanes-Oxley Act (SOX) was passed in 2002, management and auditors struggled with defining the scope of business continuity as an internal control related to financial reporting. However, as SOX compliance has become more commoditized for public companies, management and external audit firms have been able to come to a middle ground on this topic.

The most common business continuity-related controls in this area focus on system/data backups and periodic restorations of applications/environments deemed in-scope for SOX purposes. In other words, external auditors mainly want to gain comfort that management is backing up their key SOX-related systems and data on a regular basis and has methods of detecting and addressing backup failures should they occur. Further, it is not uncommon for external audit firms to confirm that management can restore systems or critical files from those backups, should the need arise. This can be evidenced by performing and documenting targeted restoration activities and proving that backed-up data is accessible and intact. Most audit firms have determined that specific business continuity or IT disaster recovery plans are not required by SOX regulations.

Regardless of how BCM and IT disaster recovery topics are treated within regulations such as SOX, most executive managers continue to advocate business continuity-related processes because they are viewed as good business practices. For service-oriented organizations (e.g., payroll services, business process outsourcing, cloud computing), business continuity is a topic that remains very near the top of the list when clients perform their annual vendor audits or issue-related audit questionnaires.

Organizations must consider unimaginable disruption scenarios as an essential component of their comprehensive crisis management program. The potential convergence of disaster events will require risk management functions to ask many bold questions. What if there is a regional power outage, with the digital infrastructure failing during a period of work from home with all the corporate offices closed? Do remote workers have the capability to perform their work given that multiple disaster events may be occurring simultaneously? What key infrastructure redundancies should be in place to address aggregate compounding disaster events that will ensure resilient enterprise operations?

— Damon Owen, Director, Protiviti
TESTING, TRAINING AND MAINTENANCE
**Q 43** What are the prevailing practices regarding the storage of business continuity planning documentation?

There is no one-size-fits-all BCM documentation storage approach. Storage practices should be guided by these two important considerations about business continuity plans: They should stay current, and they should be accessible to all personnel when needed.

A library distributed solely in hard copy would be difficult to keep updated, and even harder to confirm that all personnel are referencing current versions as needed. For BCM documents, all employees should have access to the most current versions. Further, it is far easier for those tasked with maintaining the documents to keep a primary source updated, instead of multiple versions. Typically, BCP libraries are maintained on an all-company network file share, intranet/SharePoint site, or other employee and/or third-party portals.

While accessibility is key, it is also critical to maintain security over the library of risk assessment, impact analyses, strategies and planning details, and exercise results. These documents often contain proprietary and sensitive data, including names, roles, contact information, IP ranges, procedures and partners, among others. Companies that provide goods or services may also be requested to provide these documents in whole or in part and may or may not desire to share.

Considerations should be made to maintain the classification of these documents and to ensure appropriate controls are put in place to ensure they remain secure. A library of planning materials should be accessible to personnel based on their role in the organization, their responsibilities during recovery, or the processes they support. The prevalence of mobile technologies and ubiquitous internet access means most personnel carrying personal or company-issued smartphones and tablets can access these BCM documents through cloud-based document storage and SaaS BCM software solutions as needed.

Storage decisions should be made with the goal of enhancing how quickly employees consume content and can execute on the recovery and resumption procedures. Business resumption plans may be further segmented by end-to-end processes (e.g., periodic financial reporting functions), an entire workstream (procure to pay), or, even further, to the specific responsibilities by role. The goal of this segmentation is to make it as fast and seamless as possible for all personnel to find the parts of the plan that are most pertinent to them, and then to help those people understand the immediate inputs and outputs to their processes.

**Q 44** How often should business continuity-related documentation be updated and how can organizations keep the plans current?

In general, business continuity documentation should be reviewed and updated at least annually. However, a more frequent review and update process may be required as changes in the organization occur. The business continuity team should stay abreast of changes such as mergers, acquisitions, divestitures, entry into new markets, organizational restructuring, or the implementation (or retirement/sunsetting) of technology. Key factors to consider may include:

- Business unit and associated function listing and validation of criticalities as determined in the BIA, including reassessment of maximum tolerable downtime (MTD), recovery time objective (RTO), and recovery point objective (RPO) metrics

- Risks or threats that may impact key business operations
- Business unit/function dependencies/interdependencies (IT and non-IT)
- Adoption of new technologies, including migration to private or public clouds, implementation of new enterprise application solutions, retirement of legacy systems, etc.
- Opening/closure of key office locations or facilities
- Key employee/vendor contact information
Resource requirements matrices, including insourcing or outsourcing and offshoring, nearshoring or onshoring of major functions and processes

- Onboarding of new key third-party providers
- Major changes to upstream or downstream supply chains
- Data, intellectual property and documentation storage locations, including cloud-hosted environments
- Changes to regulatory environment/reporting requirements.

Given the decentralized nature of most business continuity programs, a cross-functional team should be responsible for maintaining the crisis management and crisis communications plans, as well as updating risk assessments and business impact analyses. Business function and technology owners should be responsible for their individual resumption and IT disaster recovery plans, respectively. These plans tend to focus more on recovery of a distinct process, set of processes, or specific technology stack. While responsibility for making plan updates may lie with various individuals and/or cross-functional teams, the BCM program coordinator should oversee all changes to ensure consistency with organizational policy requirements.

Regardless of the process used, maintenance should be based first on a defined schedule. If an organizational change management process is underway, BCM should be integrated into this program.

Q 45  **How often should BCM plans be tested?**

BCM plans should be tested as often as possible, but within reason. Management expectations, test objectives, the maturity of the planning process, and system/process criticality are all factors that drive how often to exercise a team and validate strategies and plans. Most organizations test business continuity processes once or twice a year, however, this can be increased due to factors such as:

- Changes in business processes
- Changes in technology, facilities or critical vendors/third parties
- Changes in business continuity or crisis management team membership
- Changes in executive management
- Anticipated or planned events, which may result in a potential business interruption.

Organizations may also choose to conduct more tests or exercises if operations are decentralized across multiple locations. Additionally, some business continuity coordinators may choose to conduct testing in stages, given the dispersion of their personnel, the size of their IT infrastructure, the size of the business, or their relative inexperience with ITDR or BCM testing. Others may decide to rotate as many people as possible through the training experience, via a test or exercise, given the valuable benefits. Regulatory requirements may also influence the number of tests performed annually.

Lastly, IT environments change rapidly. Plan coordinators should ensure IT disaster recovery procedures are updated in tandem with established technology change management procedures. When this occurs, alignment with recovery requirements of the business should be confirmed.

No matter how many tests are conducted each year, planners should schedule them well in advance to ensure maximum participation. Also, planners should develop a progressive, incremental schedule that includes a timetable of events.
Q 46  What testing options are available for BCM programs?

Testing options for a BCM program come in all shapes and sizes. (See the Appendix for a detailed list of testing options.) Regardless of the testing option employed, the BCM team should incorporate actual data and simulate real-world conditions whenever possible, and the facilitation team should develop test scenarios based on results from the risk assessment. Additionally, teams should not ignore unlikely events that could occur (e.g., COVID-19). If the organization is new to BCM testing, it should start small and slowly work up the maturity curve. For example, management could begin by having “tabletop” discussions regarding various recovery scenarios with the business. From there, management could enhance the test to include a coordinated, sample-based recovery of applications, processes and departments, and ultimately graduate to performing a fully simulated test that includes restoring major components of the business and the supporting IT environment simultaneously.

Further, business continuity coordinators should be empowered to be original, to encourage engagement of their recovery teams, and to be creative during the testing.

The following creative measures may be considered:

- Facilitating a test like the Monopoly® board game. The test could then use "Chance Cards" to insert unanticipated variables into the test process.

- Inserting realism into testing exercises by asking key personnel to consider a localized or regional disaster (e.g., tornado or hurricane) that can result in key BCM team members or other personnel being shut out of the communication aspects of the exercise or to “sit out” the entire exercise. This would help evaluate how alternate personnel responds to the situation if key decision makers are unavailable.

- Organizations should incorporate variability in testing approaches. Conducting the same test twice a year could lead quickly to stagnant outcomes, a lack of perceived value and bored participants.

Q 47  Should organizations expand testing beyond IT?

Organizations should create a testing strategy and policy that dictates standards and guidelines for both the business and technology teams and functions. All areas of the organization can experience disruptions unrelated to the loss of technology (e.g., loss of key personnel, facilities, vendors) and need to be adequately prepared.

For non-IT business continuity tests, companies should consider testing all other facets of their programs, such as crisis management and business resumption teams and corresponding plans. Applicable testing methods may include:

- Walk-throughs of existing plans with recovery teams

- Departmental or companywide simulations in which employees must execute crisis management and/or business resumption activities, using their plans as a guide to respond to defined scenarios (scheduled or unplanned)

- Cooperative exercises with key external partners and customers

- Industrywide exercises administered by local industry organizations, trade associations or service bureaus

- Local response procedures to a regional crisis.

Furthermore, business users should contemplate and test their preparedness against scenarios in which key systems or data are unavailable for a prolonged period of time, which may be the case during a complex data center failover or during the response to a security incident (e.g., denial of service, malware). These black-swan events may be described as “extreme but plausible.” Under these circumstances, business teams may need to enact manual workarounds to continue operations and should therefore be rehearsed in their procedures and on a regular cadence.

End users can also participate in the IT team’s IT disaster recovery testing by performing validation when data is restored from backups, availability and performance testing when applications are restored, and load testing if there is any concern of making systems unavailable.
due to a high volume of users. These steps not only validate application and database servers, but also can validate connectivity during periods of high load, assess throughput and performance of the network, and test interfaces with third parties (e.g., cloud service providers, or CSPs).

Broader participation in testing can help organizations better determine their level of preparedness for dealing with disruptions. This is because various types of disruptions, including any loss or unavailability of systems and data, will require employees to perform alternative procedures. Therefore, it is imperative that representatives from across the organization participate in business continuity testing. While IT may be responsible for the recovery of systems and data, it is ultimately business users who must resume operations and delivery of services and should therefore be familiar with and rehearsed in any communications and workarounds that may be needed.

**Q 48 What are some successful business continuity training approaches?**

A common approach to business continuity training is to review formal roles and responsibilities and ensure that what is documented meets business requirements. In many cases, roles and responsibilities are boilerplate and may not be cohesive within the organizational structure or culture. After ensuring roles and responsibilities are well defined and assigned appropriately, training materials should be reviewed to ensure all roles and responsibilities are covered.

For example, as a member of the company’s crisis management team, a vice president of IT may wear multiple hats, including being responsible for initiating an IT disaster recovery response and serving as a building evacuation leader. In this example, any training regimen should address both responsibilities and ensure all components of the business continuity program remain relevant and actionable. Additionally, as part of any role-based training, alternate and tertiary personnel to a given role should be trained as well. Training a primary resource without training others who may assume that role during an actual event introduces considerable risk.

Content can be delivered in numerous ways, but it is critical that any multi-site organization provide the same quality and cadence of training anywhere a defined role is represented. In an actual event, senior management needs to know that local decisions will be made consistently, and that each person in a specific role knows the responsibilities and defined course of action.

For most organizations, some level of customized training is necessary, depending on their individual priorities. Many larger organizations have found a matrix training system to be a very effective complement to facility-based training. In these approaches, crisis management, business resumption and IT disaster recovery personnel at each site are trained together. This approach improves standardization and dissemination of best practices without compromising the specificity required in plans covering a call center, manufacturing plant or other facility.

---

Regulatory compliance is a key consideration when planning and strategizing about how to develop and implement an enterprise business continuity and resilience program. Not only is this sound practice, but business continuity is a discipline enforced by a growing number of regulatory requirements worldwide.

— Dugan Krwawicz, Associate Director, Protiviti
How does BCM awareness differ from BCM training?

Awareness is an inherent part of training; however, training is not necessarily part of awareness. These terms are often used interchangeably, but they represent different levels of involvement as they relate to business continuity.

Awareness implies that one possesses knowledge of the BCM program or related activities. For example, the company may distribute an email communication pointing employees to an internal repository that houses business continuity plan documents and asking that they familiarize themselves with the materials. However, awareness does not necessarily imply that one has knowledge of how to execute the business continuity plan.

Role-based training, on the other hand, is a stricter regimen that pertains to receiving specific instruction on how to execute business continuity plan activities and solidifying that instruction with recorded proficiency exercises. This instruction may be provided through classroom, computer-based, test-based, and/or instructional guides and templates.

What certification options are available for BCM practitioners?

There is no shortage of certifications in the business continuity space. Nonetheless, rather than selecting the first certification option that appears through a Google search, people seeking BCM certification must first decide why they are getting the certification in the first place. Do you own a BCM program at your company? Are you in a professional services role and looking to offer consultative advice about BCM to your clients? Are you an internal audit practitioner seeking to broaden your knowledge on auditing your company’s BCM program? These questions will offer guidance on which certification option would be the most appropriate for you and your respective circumstance.

Below is a sample of organizations and respective certifications:

• The Disaster Recovery Institute International, or DRII International (also known as DRII) — DRII offers several general certifications, including Associate Business Continuity Professional (ABCP), Certified Functional Continuity Professional (CFCP), Certified Business Continuity Professional (CBCP) and Master Business Continuity Professional (MBCP), but they also offer other BCM-related certifications focused on specific areas such as vendor, audit, cyber resilience, healthcare continuity, public sector continuity, and risk management.

• The Business Continuity Institute (or BCI) — BCI offers a Certificate of the Business Continuity Institute (CBCI), which is the first step to proving your industry knowledge and joining the BCI’s global network of business continuity and resilience professionals.

• International Organization for Standardization (ISO) — ISO 22301 is an international standard for business continuity management. The ISO organization offers the Certified ISO 22301 Business Continuity Manager accreditation for practice professionals related to this standard.

• Business Resilience Certification Consortium International (BRCCI) — The BRCCI provides business continuity and IT disaster recovery training and certification services. Their mission is to deliver world-class training and certification programs focused on management and planning of business continuity and IT disaster recovery.

It is important to note that most BCM certifications mandate annual education and CPE requirements to preserve your accreditations.
FINANCIAL SERVICES
Ensuring continuity of operations has long been a foundational consideration for financial institutions when it comes to supporting clients and stakeholders. That focus has only increased over the past several years as organizations transition to new customer-centric services, cloud platforms and other ways of automating their operations. As the industry evolves and risks escalate, maintaining a clear understanding of how to strategically prepare for, respond to, and recover from major disruptive events has never been more critical for financial institutions.

Concerned about the changing risk dynamic, financial regulators are also increasingly focused on continuity of operations. In addition to updating existing guidance and regulations, a number of regulators have proposed rules aimed at strengthening the operational resilience of financial institutions. As explained in the section on Business Continuity Management Basics, operational resilience is a logical extension of existing business continuity management elements. Under operational resilience, firms that support important business services that customers (and the broader economy) rely on are expected to demonstrate their ability to respond to “extreme but plausible” scenarios effectively.

Q 5.1 What regulatory guidance and standards should financial institutions rely on?

Depending on organizational type, U.S. depository institutions may be subject to various regulations and guidance from bodies such as the Board of Governors of the Federal Reserve System (FRB), the Federal Deposit Insurance Corporation (FDIC), the National Credit Union Administration (NCUA), the Office of the Comptroller of the Currency (OCC), and the Consumer Financial Protection Bureau (CFPB). For business continuity specifically, the Federal Financial Institutions Examination Council (FFIEC) maintains a standard Business Continuity Management booklet, which describes principles and practices for IT and operations for safety and soundness, consumer financial protection, and compliance with applicable laws and regulations. The principles in the booklet are designed to guide examiners in evaluating financial institution and service provider risk management processes to ensure the availability of critical financial services. Examiners expect financial institutions to apply the guidance and often benchmark against the principles and practices outlined as part of an assessment.

U.S. non-depository financial institutions should look to guidance provided by the Securities and Exchange Commission (SEC), the Commodity Futures Trading Commission (CFTC) and the Financial Industry Regulatory Authority (FINRA). Sometimes institutions come together to issue joint advisories on business continuity. A good example of this is the interagency business continuity and disaster recovering planning guidance issued by FINRA, CFTC and the SEC following Hurricane Sandy in October 2012. Websites for each of the agencies also contain agency-specific information on business continuity and pandemic preparedness requirements for supervised firms.

In Europe, the European Banking Authority’s Guidelines on Internal Governance (GL44) provides a consolidated view of supervisory expectations on transparency of the corporate structure, the role, tasks and responsibilities of the supervisory function on IT-systems as well as business continuity management. Increasingly, the European Commission is focusing on digital operational resilience of the financial sector, particularly in the areas of information and communications technology and security risks. There is also the Basel Committee on Banking Supervision’s “High-Level Principles for Business Continuity,” outlining key considerations that banks must incorporate regarding business continuity and disaster recovery.

Across the Asia-Pacific region, the Australian Prudential Regulation Authority (APRA), the Monetary Authority of Singapore (MAS) and the Hong Kong Monetary Authority continue to issue new and updated guidance on business continuity. It is worth noting that many of APAC regulators look to international standards, such as the ISO, to shape their respective guidance. As an international organization, ISO’s business continuity management standards, like ISO 22301/ 22313, blend the requirements from several national standards, including those from the United States, Japan, Singapore, Canada, and Australia.
Q 52 How has U.S. regulatory guidance on business continuity changed in recent years?

The most notable recent update to existing BCM guidance came in the form of an updated FFIEC handbook in November 2019. The revised business continuity management booklet offers increased clarity, with detailed examples designed to make it easier for financial institutions to comply with its guidance and to help examiners determine whether management are addressing risks related to the availability of critical financial products and services.

The detailed examples in the latest booklet cover various phases of the BCM lifecycle, from governance to aligning BCM elements with the organization’s strategic goals, developing a business impact analysis, conducting a risk assessment to identify risks, and creating effective strategies for resilience and recovery objectives. It walks through the process of establishing a business continuity plan, disaster recovery plan and crisis management plan, as well as implementing a training program, conducting exercises and tests, updating and improving all programmatic components, and reporting and monitoring.

One of the most significant changes in the new booklet is its emphasis on risk identification and risk assessment, such as the likelihood of impact of different threat categories. For instance, it describes the speed of onset or velocity of a threat, the size of the affected area, and how to assess the likelihood of impact appropriately. Another crucial update is the inclusion of a business impact analysis recovery objective timeline. This is helpful because it describes key concepts such as recovery point objectives, recovery time objectives, maximum tolerable downtime, data loss potential, and critical disruption points. These concepts are more fully defined in the new version than in the previous.

Q 53 What is operational resilience and how is it relevant to business continuity for financial institutions?

In July 2018, UK supervisory authorities (the Bank of England, the Prudential Regulation Authority and the Financial Conduct Authority) brought the concept of operational resilience into the limelight, with the publication of a joint discussion paper, titled Building the UK Financial Sector’s Operational Resilience. Since then, other regulators have followed suit by issuing proposals on enhancing the resilience of financial institutions. Most recently, the Basel Committee released a consultation paper with proposals intended to strengthen banks’ ability to withstand significant operational failures or wide-scale disruptions.

Operational resilience is defined by the UK supervisory authorities as “the ability of firms and financial market infrastructures and the financial sector as a whole to prevent, adapt, respond to, recover and learn from operational disruptions.”

Firms are expected to take ownership of their own operational resilience by following a set of approaches or a framework, which includes identifying their important business services; setting an impact tolerance for each of these services; quantifying the maximum acceptable level of disruption through severe but plausible scenarios; identifying and documenting (also known as mapping) the necessary people, processes, technology, facilities and information required to deliver each of their important business services; and performing a self-assessment of their operational resilience.

Q 54 How should firms consider third party-related risks as a component of business continuity management?

According to a 2019 survey by the UK Financial Conduct Authority, third parties are the second biggest root cause of operational outages — after change management. Supply chain disruptions can have a significant impact on key business processes and undue concentration of services among shared service providers, such as cloud providers, can also have dire consequences if ignored or left unmanaged. Firms need to understand their third-party relationships well and remember...
that regulators will hold them responsible for the work (or failures) of third parties. As such, incorporating the third parties into their continuity planning is critical. Businesses should obtain assurances and verify that their key third parties are maintaining robust controls.

Beyond contractual obligations, firms should take steps to improve their understanding of how vendor outages can impact their own operations. They should proactively understand and address third parties along the critical path of business services, working with them to monitor and respond to events. This includes actively engaging the vendors in testing, exercises, and planning activities.

Q 55  Are financial institutions, such as banks, required to recover disrupted operations within a defined time period?

There is currently no regulation or legislation-defined rules mandating specific recovery time objectives for institutions. However, regulators do have a clear expectation that entities will establish their own recovery objectives based on widely used standards such as RTO, RPO, MTD, and impact tolerance, to name a few. Firms are expected to set recovery objectives based on a rational understanding of the potential impacts of an unplanned and undefined disruption. The expectation is that each organization would apply these standards as outlined in the FFIEC booklet. Recovery time objectives of processes and systems should be established through a business impact analysis. The likelihood of risk and an understanding of cost benefit should be factored into this analysis and as part of the firm’s broader risk management program. An examiner would typically assess the work performed and determine whether the conclusions reached around recovery are reasonable.

Q 56  Are business continuity standards for financial institutions set only by the regulatory agencies?

The U.S. Department of Homeland Security (DHS) also offers guidelines, which it defines as “a vital component” of U.S. critical infrastructure, to the financial services sector. In 2010, the agency, in partnership with the U.S. Department of the Treasury, published a sector-specific plan that details how the National Infrastructure Protection Plan (NIPP) is implemented within the financial services sector. The NIPP provides a risk management framework designed to enhance the safety of U.S. critical infrastructure. The DHS’ Banking and Finance Sector-Specific Plan: An Annex to the National Infrastructure Protection Plan provides a description of the complex nature of the sector and an overview of its products and services. The products and services are:

- Deposit, consumer credit, and payment systems
- Credit and liquidity products
- Investment products
- Risk transfer products (including insurance)

The plan underscores the interconnectedness of the financial services sector to other critical infrastructure sectors, such as communications and IT. These critical infrastructure sectors, if disrupted, would undermine the financial services sector’s ability to conduct normal business. The plan also lays out the following vision statement on business continuity: “To continue to improve the resilience and availability of financial services, the banking and finance sector will work through its public-private partnership to address the evolving nature of threats and the risks posed by the sector’s dependency upon other critical sectors.” Additionally, these three goals for the financial services sector are outlined:

- Achieve the best possible position in the face of myriad intentional, unintentional, man-made, and natural threats against the sector’s physical and cyber infrastructure;
- Address and manage the risks posed by the dependence of the sector on communications, IT, energy and transportation systems sectors; and
Work with the law enforcement community, financial regulatory authorities, the private sector, and counterparts outside the United States to address threats facing the sector.

Q57 **To what extent are financial institutions responsible for the business continuity of vendor-supported systems?**

Regulators expect financial institutions to establish acceptable business continuity plans for all systems required to perform key activities, including systems used for customer-facing, financial reporting and compliance (e.g., AML transaction monitoring and sanctions screening). For vendor-supported systems, a financial institution’s due diligence procedures should consider the vendor’s business continuity standards and practices, as well how those standards and practices align with their individual needs. Contracts with vendors should reflect obligations and expectations, and financial institutions should consider participating in vendor business continuity tests or, at minimum, require evidence (such as SOC reports) that the program has been consistently maintained and regularly tested.
Healthcare organizations are facing multiple challenges in the development and maintenance of emergency preparedness operation and recovery plans. Along with increasing regulatory scrutiny, such as The Joint Commission’s reinstatement of the survey process to dealing with simultaneous events and the recent increase in natural disasters, such as the COVID-19 global pandemic, healthcare organizations are being asked to adhere closely to current mandated emergency preparedness standards.

While this guide does not present the many details surrounding each potential variable that healthcare organizations may want to take into account when developing and/or assessing the strength of their emergency management program, all healthcare organizations should at least consider the points highlighted below (in addition to the industry-independent considerations already discussed in this publication).

Q 58 How can healthcare organizations ensure their emergency preparedness plans meet current regulatory requirements?

Both the Centers for Medicare & Medicaid Services (CMS) and The Joint Commission are advising healthcare organizations to ensure their readiness for an all-hazards approach to emergency management is a top priority. With the increased likelihood for simultaneous events, such as a global pandemic occurring at the same time as natural disasters like hurricanes and wildfires, organizations that are not prepared to bring their facilities and systems up to compliance would face significant challenges. Not only will lives depend on organizations being prepared and compliant, but the future of the organization as a key contributor to the healthcare infrastructure could also be at stake.

Developing an emergency preparedness plan that is consistent with regulatory requirements is no simple task. Healthcare organizations should be continually developing, refining and executing all emergency preparedness plans to meet not only regulatory expectations, but more important, to increase their readiness to respond effectively to an emergency situation when it occurs.

To meet all the requirements, at a minimum, healthcare organizations must consider undertaking the following activities:

- Engage in planning activities prior to developing a written emergency operations plan, which is a critical component of the emergency preparedness plan.
- Engage leaders to help develop and maintain a written emergency operations plan that describes the response procedures to follow when emergencies occur. The plan also should include identification of the healthcare organization’s capabilities and response procedures for when the organization cannot be supported by the local community to provide communications, resources and assets, security and safety, staff, utilities or patient care for at least 96 hours.
- Conduct a hazard vulnerability analysis (HVA) to identify potential events, and rank them based on probability, severity and organizational risk. Through the HVA, organizations can work with community partners to prioritize the potential emergencies identified, communicate needs and vulnerabilities to emergency response agencies, and identify the community’s ability to meet its needs.
- Develop a communications plan to help facilitate how the healthcare organization connects with staff, external authorities, patients and their families, media, suppliers, vendors, and others regarding the emergency; to update local, state and federal authorities; and to connect with identified alternative care sites. The communications plan must include any backup systems and technologies utilized, how resources and assets will be managed during emergencies, how the organization will obtain and replenish medications and supplies, as well as share resources and assets with other local healthcare organizations; and arrangements for transporting patients, managing security and safety during an emergency, managing hazardous materials and waste, and managing utilities, water and fuel. Memoranda of understanding should be created for all community resource partners.
Staff must be trained for their assigned emergency roles to determine how the organization will manage patients during emergencies. For example, develop a plan for keeping patients on the premises or evacuating them if the facility is not safe; determine how the organization will manage scheduling, triaging, assessing, treating, admitting, transferring and discharging patients; and finally, define how the organization will manage any increase in demand for services, medications, patients’ personal hygiene and sanitation needs, mental health needs, dietary needs, and mortuary services.

Disaster privileges need to be granted for volunteer licensed independent practitioners during emergencies. Determine how volunteers will be distinguished from regular staff and who will oversee their performance, addressing any state or federal waivers.

Perform an evaluation of the effectiveness of the healthcare organization’s emergency management planning activities. This should include activating the emergency operations plan twice a year and conducting an annual exercise that includes an influx of simulated patients. In addition, the organization should conduct an annual exercise that includes participation in a communitywide exercise.

Recovery strategies and policies need to be developed for mandated after-action reports and business and emergency operation plan modification from lessons learned.

A business continuity plan is an essential component of emergency management recovery. Ensuring that patients continue to receive appropriate care and healthcare providers are able to respond to major events in the community are driving forces behind much of what a healthcare organization’s BCP entails. The clinical implications of having an effective or ineffective BCP are too numerous to be addressed in this document. A BCP must protect the organization’s physical plant, IT systems, financial and clinical operations, and other infrastructure from direct disruption or damage so that it can continue to function throughout or shortly after an emergency. BCPs assist healthcare facilities in meeting their business resilience and recovery needs, as well as meeting regulator guidelines for recovery, as the goal of regulators is an effective and efficient return to normalcy or a new standard of normalcy for the provision of community healthcare delivery. A healthcare organization’s geographical reach and the breadth/depth of its strategic initiatives also must be taken into consideration in its BCP efforts.

Business continuity plans need to be tested. The type and extent of testing requirements will ensure a healthcare organization’s BCP is designed effectively and everyone involved is trained and aware of their responsibilities. Also, testing requirement may vary significantly based on the type of organization and state of operation.
Q 59 Does the Health Insurance Portability and Accountability Act (HIPAA) include a requirement to implement BCM processes?

Several aspects of BCM are included in the security section of the HIPAA requirements. Specifically, HIPAA (Section 164.308) calls for:

- Risk Analysis (required) — §164.308(a)(1)(ii)(A)
- Contingency Plan — §164.308(a)(7)(i)
  - Data Backup Plan (required) — §164.308(a)(7)(ii)(A)
  - Disaster Recovery Plan (required) — §164.308(a)(7)(ii)(B)
  - Emergency Mode Operation Plan (required) — §164.308(a)(7)(ii)(C)
  - Testing and Revision Processes (addressable) — §164.308(a)(7)(ii)(D)
  - Application and Data Criticality Analysis (addressable) — §164.308(a)(7)(ii)(E)

As noted above, the business continuity-related provisions of HIPAA are designated as either required or addressable. In terms of HIPAA, addressable does not equate to optional. Addressable simply means the organization must assess whether or not the requirement makes sense in its environment; if not, then a similar provision should be in place to act as a compensating control with the intent of performing the same type of safeguard. According to the U.S. Department of Health and Human Services (HHS), decisions made regarding addressable specifications must be documented.

Additionally, HIPAA Section 164.310 requires contingency plans for facility access and security. Section 164.312 requires procedures to gain access to protected health information (PHI) during an emergency. A common misconception is that the HIPAA requirements are focused exclusively on IT. Although most of the Final HIPAA Security Rule can be perceived to be focused heavily on IT, PHI is found in many forms, and the Emergency Mode Operation plan is not truly an IT issue at all. Rather, this requirement addresses how the provider will continue to protect PHI if normal IT controls are not available or functioning appropriately, which could have a significant impact on the organization's ability to continue operations in an acceptable manner, if not handled appropriately.

Q 60 Does The Joint Commission require business continuity planning for hospitals?

The Joint Commission requires that healthcare organizations have an integrated emergency management plan, including policies and procedures that address the organization's identification of its emergency preparedness; response and recovery activities that are coordinated with an organization's integrated program, including a hazard vulnerability analysis, acquisition and storage of clinical supplies, staff assignments, emergency protocols and continuity of operations planning. Business continuity plans assist healthcare facilities in meeting their business resilience and recovery needs, as well as meeting The Joint Commission Emergency Preparedness Program’s Healthcare Preparedness Capability and Healthcare System Recovery initiative, the goal of which is an effective and efficient return to normalcy or a new standard of normalcy for the provision of healthcare delivery. Continuity of operations planning ensures the ability to continue essential business operations, patient care services and ancillary support functions across a wide range of potential emergencies. The healthcare organization's continuity of operations planning may be an annex to the organization's emergency operations plan and, during a response, should be addressed under the incident command system.
TECHNOLOGY, MEDIA AND TELECOMMUNICATIONS
What are some of the supply chain considerations for Technology, Media and Telecommunications (TMT) organizations?

TMT industry group organizations with hardware manufacturing operations around the world need to take the appropriate steps to guarantee that required supplies and materials are available in each region. Supply chain strategies focused on just-in-time models and single-source providers may need to be revisited. As became evident during the COVID-19 global pandemic, effective business continuity planning around the supply chain likely involves ensuring that TMT companies have more than one source for key supplies and materials. Diversifying the supply chain is key so that it is not concentrated with one supplier or a small group of suppliers, or within a specific geography.

How should TMT organizations address or revamp their research and development programs to ensure business continuity?

TMT organizations can benefit from building redundancy into their research and development (R&D) operations. Unforeseen events and business interruptions such as the COVID-19 global pandemic make it clear that establishing R&D operations in just one location or region results in concentrated risk. TMT organizations should consider how they might diversify R&D efforts in different locations around the world, as it is less likely that all of them would experience the same level of interruption.

More broadly, TMT organizations also might consider how they can transform their R&D operations. The type of precision equipment required and clean-room setup that are part of R&D activities prevent this work from being conducted remotely. While it is not possible in every instance, TMT organizations should take a strategic look at their R&D function to assess how they might reinvent it so that progress can continue amid significant business interruptions.

Consider that for some TMT organizations, R&D activities increased notably during the COVID-19 pandemic, but for others they stopped entirely, as onsite facilities were unavailable. Formulating innovative solutions to these challenges will be key for TMT organizations going forward. One path more companies are likely to take is diversification in their R&D operations around the world.

What are some other key considerations for TMT organizations to address as part of their business continuity planning?

Resources — both human and physical — are key areas for TMT organizations to address in their business continuity management efforts. During the COVID-19 pandemic, many TMT organizations experienced surges in demand in areas including, but not limited to, product delivery, customer service, online traffic (e.g., streaming content) and network bandwidth. TMT organizations should consider the capabilities within their infrastructures to accommodate growth quickly if events and, more important, customers and clients demand it.

From a people perspective, TMT organizations, like those in any other industry, need to have strong communications plans to keep their workforce engaged continually during
a major business interruption that necessitates employees working remotely for an extended period. For example, the COVID-19 pandemic resulted in interruption of key functions such as accounting, finance, customer service and help desk in many organizations. To ensure improved continuity of service in these and other core functions, TMT organizations might explore utilizing managed services or variable labor models that are designed to maintain operations and activities even amid a major business interruption.

TMT organizations also can benefit from conducting deeper and more frequent scenario-planning exercises to consider how to manage through unanticipated events and their effects. What is the response if a large percentage of the customer base seeks to renegotiate contracts or agreements? What if revenue is impacted severely by one or more types of unanticipated events or business interruptions? What is the plan for the organization to manage through the crisis? This last point is especially relevant for emerging TMT companies that may have just one revenue stream or a small number of them. Effective business continuity management might call for exploring strategies to diversify the business so that it can, at least partially, offset the effects of a major business interruption.

Finally, like companies in many other industries, TMT organizations should consider their overall network and data security posture. The COVID-19 global pandemic forced millions of employees to work remotely, creating new and sometimes fertile ground for cyberattacks and bad actors to flourish. TMT organizations, given their heavy reliance on digital and cloud-based environments, should ensure that their cybersecurity measures are not only up to date but also resourced appropriately to manage the many changes that can occur during any business interruption.

Q 64  What are the best practices for ensuring the availability of critical infrastructure for the communications industry?

Customers have evolved over the years to demand more network availability and performance from communications companies. As a result, these organizations have increasingly focused on the deployment of processes, systems and supporting infrastructure designed to eliminate or minimize the impact of disasters or network outages.

Key areas to consider include, but are not limited to, the following:

- **Topology** — The network topology should be developed to withstand network disruption. It may include redundant paths for transmission networks for critical network elements. Further, the organization must monitor the transmission capacity for each redundant path. Testing of redundant paths should be included as part of disaster recovery testing.
- **Redundancy** — The critical network infrastructure should be deployed with geo-redundancies. This may include active-active or active-standby configuration.
- **Data centers** — Communications organizations should consider the deployment of data centers in multiple geographic regions. Redundant network elements should be deployed in separate data centers.
- **Preventive maintenance** — The critical network infrastructure elements, especially without redundancy, should include frequent health checks and preventive maintenance activities to minimize unplanned outages.
- **Backup** — The backup strategy and processes should be aligned with recovery point objectives. Organizations should conduct storage and validation of backups in alignment with defined policy.
- **Spare parts** — Communications organizations should have a defined strategy for managing spare parts. Buffer stock should be considered for critical infrastructure at each location. Further, the deployment of a multivendor network infrastructure should include spare parts for each location.
- **People** — Cross-training of employees should be considered to ensure the availability of resources for performing critical tasks in case of network unavailability.
Q 65  What are some key considerations in incident management planning for the communications industry?

The communications industry requires a robust incident management plan due to multipronged threats covering network operations, cybersecurity, and physical infrastructure-like buildings and data centers. The following areas must be considered in incident management planning:

• **Functional alignment** — Incident management planning usually covers the network operations center, security operations center and physical security. Typically, a separate department deals with each of these areas, leading to multiple incident plans. The organization must ensure alignment of each incident management plan with the corresponding impact analysis. Further, the organization should define escalation criteria, including the invocation of a crisis management plan.

• **Crisis management planning** — The crisis management plan should be developed and documented with enough flexibility to address any type of reported incidents. It may include multiple emergency response teams depending on the type and nature of the event. For instance, the response team for network equipment failure would be different from one to address a physical threat to a data center.

Q 66  What are some vendor-related technology considerations in business continuity planning for communications organizations?

Communications organizations work with numerous technology vendors that provide, for example, telecommunications and IT equipment, as well as security infrastructure. Network operations are sometimes outsourced to vendors as well. Vendor risks are cascaded to the organization’s risks. Therefore, they should be an essential component in business continuity planning.

Vendor-related issues for communications organizations to consider include, but are not limited to, the following:

• **Contractual requirements** — As part of the vendor contract, the organization should state all expected business continuity requirements, depending on the area of scope. These may include incident and disaster management plans, inventory requirements, information backups, and preventive and health check activities.

• **Disaster recovery plan** — Vendors may be required to submit disaster recovery plans, especially for areas related to network operations. These plans should be aligned with the organization’s requirements and its recovery point and time objectives. Moreover, these plans should be tested in alignment with the organization’s BCM policy.

• **Incident management plan** — The vendor’s incident management plan should adhere to the organization’s incident policy. It may include the alignment of escalation and impact criteria, workflow requirements and evidence collection requirements.
What are some of the key technology-related challenges faced by communications organizations in maintaining an effective business continuity program?

Communications organizations face unique business continuity planning challenges due to the large number of IT and telecommunications systems they leverage. They should review the following areas on a periodic basis to ensure the alignment of the business continuity program.

• **Network changes** — Due to the size and number of network systems in communications organizations, they are among the top challenges these organizations must address in maintaining their BCM program. Network changes occur due to factors including, but not limited to, new technologies, patch upgrades, network optimization and network faults. These changes may accumulate over time and alter business continuity requirements significantly. Therefore, the BCM program must continuously monitor network changes.

• **Disaster recovery testing** — The critical infrastructure may limit the ability and type of disaster recovery tests performed by the organization. These tests should be scheduled to minimize the impact on the business.

Resources — both human and physical — are key areas for TMT organizations to address in their business continuity management efforts. TMT organizations should consider the capabilities within their infrastructures to accommodate growth quickly if events and, more important, customers and clients demand it.
CONSUMER PACKAGED GOODS/RETAIL
The ability of retailers to adapt to changing conditions and recover rapidly from unexpected natural events, accidents or deliberate attacks can be critical to maintaining customer loyalty and brand reputation, as well as their competitive advantage in the market. The COVID-19 global pandemic put a strain on consumer packaged goods and retail companies’ resilience and showed that a BCM program set up to respond to this specific crisis scenario has been decisive for an organization’s survival and transition to the “new normal.” Companies that were prepared to shift their business operations from their brick-and-mortar stores to e-commerce had more chances to contain losses. Likewise, organizations that did not rely on a centralized distribution strategy were able to reduce their supply chain disruption risks and maintain product availability, thanks to a broader warehousing and distribution facilities network. Retailers that had emergency procedures in place and had properly trained employees at each location were able to limit the rate of infection and ensure the safety of their employees and customers, reducing the operational and reputational risk of such a disruption.

Many retailers and consumer products organizations must revisit the cost-benefit analysis of their business continuity strategies and operational risk tolerance, with greater focus on the impacts of widespread events affecting the entire supply chain — from sourcing, through manufacturing and distribution and up to the point of sales. They also must address and plan for potential events — such as technology outages, critical supplier unavailability or natural disasters in areas where key operations and facilities reside — that can adversely affect business continuity.

Q 68  What is the impact of omnichannel strategies on the business continuity plan?

Consumers are rapidly shifting their behavior toward e-commerce. For retailers, it’s more important than ever to have the ability to shift their customers seamlessly from one channel to the other (e.g., physical stores, e-commerce, social media), not only in the sales processes but also for various communications and customer engagement activities. In this new environment, IT systems availability is critical to maintain and preserve retailers’ digital life. Recovery time objectives need to be reviewed in order to reduce downtime in the event of a business interruption and to enable continuous delivery of a seamless and personalized cross-channel customer experience.

Q 69  Do organization’s business recovery strategies consider stock keeping units (SKU) optimization?

In the event of a supply chain disruption due to the unavailability of raw materials or finished/semi-finished products, default of suppliers or subcontractors, or events affecting the organization’s main manufacturing, warehousing and distribution facilities, it is good practice to prioritize the production of high-demand/best-seller products, versus products for which there historically is fluctuating demand, to maximize revenues until operations return to normal. This analysis should also consider that unexpected changes in consumer behaviors might occur, increasing the demand for specific products (or SKUs) at the expense of other products in inventory.
Q70  How should global trade tensions be considered in the BCM program?

Consumer packaged goods and retail companies should evaluate the risks of a trade war involving emerging markets and significant macroeconomic changes (e.g., Brexit), and evaluate the impact of an import tariff increase or a restriction on imports to their business. This analysis should consider the overall reliance on a foreign country, including manufacturing plants, critical vendors and suppliers, logistics facilities, the likelihood that the country could be involved in a trade war in the future, or the medium- and long-term effects of an existing trade war. In the event of business concentration in high-risk areas, mitigation strategies should be implemented to reduce the impact of a business interruption or slowdown due to a trade war (e.g., reduce imports and differentiate sourcing).

Q71  Should customer service be included in a business continuity plan?

Customer service typically is not considered to be a critical process for retail operations in the event of a short outage (e.g., a few days). However, customer relationship processes become more critical as recovery time becomes longer. In the event of an extended business interruption, customers might need information about deliveries, product availability and online payments, among other areas. A company’s failure to communicate with customers and clients during an outage might negatively impact its brand reputation and customer loyalty, especially in an omnichannel/multichannel environment. Business continuity plans should consider resumption solutions for customer service. Contract agreements with external vendors should include business continuity requirements that can adequately support the company’s recovery objectives.
Q 72  Can BCM planning account for complex, international supply chains that can be disrupted by geopolitics?

BCM programs should be developed in a manner that accounts for all levels of risk for the organization. In the energy and utilities space, this includes well-thought-out considerations of the complexity of their supply chains and should account for multiple contingencies, including geopolitical conflict that can impact these supply chains. Business continuity professionals should engage with all supply chain partners to identify appropriate contingencies to maintain critical operations.

Q 73  Should field sites and operational plants have their own business continuity plans?

This depends on the governance of the organization. Some have an enterprise continuity plan with flexibility to account for additional contingencies specific to field sites, refineries and plants. Other organizations have separate business continuity plans for operational sites and supporting offices. Either way, it is important that an organization has appropriate contingencies, with corresponding collaboration and communication strategies outlined for operational facilities so that critical operations can be maintained.

Q 74  Why is having a business continuity program in place especially important for the energy industry?

Having a business continuity program in place is important for a few reasons. First, energy and utility organizations must consider the safety of their employees, visitors, guests, partners, contractors, vendors and other third parties. Next, many organizations may already have environmental, health and safety procedures in place; however, mature crisis management plans and other business continuity plans (depending on the crisis) should run in parallel to ensure there is an organized response and communication from leadership. Further, enterprise risk management is not comprehensive if the BCM posture is not mature. Lastly, energy organizations are highly reliant on IT and other power/utilities and systems to run their operations. A delayed response or recovery time can result in a significant impact to the sector, revenue loss, reduced production, and potential reputational damage due to the increased market and social media attention that likely would result. Having resilience measures and business continuity strategies and plans in place is critical to minimizing these impacts.

Q 75  What type of outages should energy and utility organizations plan for?

All energy and utility organizations should perform a continuity risk assessment to identify the highly likely and highly impactful scenarios that could impact them. Based on those identified risks, they should develop recovery strategies and incident response plans. A few examples are:

- Cyber incident response plan
- Hurricane response plan
- Pandemic plan
- IT/power outage plan
Over the past few decades, manufacturers have been consistently trying to eliminate redundancies by streamlining their processes and consolidating their supply chains. In the midst of recent events, such as the COVID-19 pandemic, trade wars and other natural disasters, manufacturers have faced significant disruptions to their business. The challenges facing manufacturers range from supply chain disruptions to potential product defects to IT systems failures. Managing risks that threaten business continuity is even more challenging, often requiring more resources for global manufacturers due to inherently more complex supply chains and dynamic organizational relationships.

In light of recent events, manufacturers must critically analyze their organizations to ensure risks threatening business continuity are appropriately mitigated, including for those events that were considered “black swans.” Manufacturers should begin by thoroughly reviewing their supply chain, including every supplier that helps support it, to assess risk fully and determine alternatives to replace any essential “cogs” in the machine should they fail. Additionally, manufacturers must consider other factors, such as the use of just-in-time inventory management, co-manufacturers and single-site manufacturing, and their associated risks and benefits, when assessing the organization’s business continuity.

While this guide cannot present the many details surrounding each potential variable that manufacturers may want to take into account when developing and/or assessing the strength of their BCM programs, all manufacturers should at least consider the following questions (in addition to the industry-independent considerations already discussed in this publication).

**Q 76** How can pursuing a single-source supply strategy affect my organization’s overall risk of business interruption?

Supply strategies are complex by nature. There are many instances where a single-source supply strategy is the right business decision, even when alternate sources of supply exist. In instances where a company is reliant on a sole-source supplier, finding alternates is more daunting, as it may require changing product specifications or working closely with other key suppliers to develop alternatives. Neither of these approaches is typically fast. Furthermore, moving to an alternate supplier may carry the risk of quality issues and must be managed carefully. Supplier relationships honed over a period of years cannot be replaced overnight with an expectation of comparable performance levels.

As manufacturers streamline their supply chains and rely more heavily on single- and sole-source suppliers, they are discovering new organizational risks they have not measured. Even in cases where companies do measure the financial risks of a certain supplier (e.g., credit risk), they may not have considered business interruption risks stemming from a man-made or natural disaster. The COVID-19 pandemic brought supply chain risk to the forefront as companies, economies and even countries have struggled to appropriately source critical goods, including personal protective equipment. Single- and sole-source vendors should be included in a manufacturer’s risk assessment, business impact analysis, continuity strategy and business continuity planning. These critical vendors are key “cogs” to the effective operations of these organizations and should be treated no different from any other internal critical function or process. Additionally, pandemic, political and natural disaster risks, such as COVID-19, trade wars or wildfires, and their impacts on revenue and operations, should be measured; lead times need to be understood; alternate sources for critical supplies should be identified; and strategies to mitigate the impact of business interruptions occurring among key suppliers need to be developed.
Q 77  Has management designed manual backup procedures to carry out manufacturing schedules and order releases?

Most modern manufacturers have switched to automated manufacturing resource planning and enterprise resource planning systems. Therefore, many have not considered manual workarounds to carry out manufacturing schedules and order releases during an outage. If management does not have the confidence in the resumption capabilities of its IT systems, it should consider developing manual backup procedures to facilitate the continued operation of critical manufacturing processes. It is especially important for manufacturers to think through how these manual workarounds will be executed if their onsite workforce is disrupted. Alternatively, mothballed systems could be utilized to continue operations in the event of a prolonged disruption. In light of recent global events, these systems may provide manufacturers with a unique alternative to deal with various risks that could impact the company’s IT infrastructure.

Q 78  How do companies that rely solely on single-site manufacturing or centralized operations plan for the impact of a long-term outage?

Over the past two decades, globalization, outsourcing, increased cross-border sourcing, IT and shared services centers have encouraged many organizations to consolidate facilities and streamline processes to eliminate nonessential and redundant activities, as well as to focus and automate remaining activities. The waves of total quality management, process reengineering and Six Sigma process improvements have created a bias for strong supplier relationships and tight coupling with supply chains, with the objective of driving down costs of processes and products while preserving quality standards.

As such, manufacturers may rely solely on a single site for manufacturing of specific products, as opposed to building redundant, or multiple, manufacturing operations to meet total demand for their products. However, considering that the COVID-19 pandemic caused operations to be shuttered in specific cities, states and even countries for extended periods of time, it is important for manufacturers to evaluate the capital cost of retaining multiple sites of operation, with the potential benefit of continued manufacturing during times of crisis. Alternatively, they should consider gaining access to other production facilities that could be retooled in a timely manner to minimize a prolonged disruption.

Q 79  How do companies that utilize just-in-time inventory production methods ensure continuity in operations during disruptions?

In order to reduce the carrying cost of inventory, many manufacturers have continued to decrease inventory levels and adopt just-in-time (JIT) manufacturing and delivery techniques. Having minimal inventory on hand exposes JIT manufacturers to potential disruptive events. Any impacts to supply chain, especially in the case of sole-source or single-source suppliers, can cause issues for these manufacturers to produce promised goods to their end customers. JIT manufacturers must consider the use of multiple suppliers for key inputs and storing additional inventory to combat possible business continuity risks, while also considering the potential trade-offs in quality, time and cost.
Q80 How can manufacturers that utilize third-party co-manufacturers ensure minimal disruptions from these organizations?

Whether it be component parts or fully developed products, it is becoming increasingly common for large manufacturers to outsource a portion of their operations to third parties. As with any third-party relationship, it is important to ensure the organization has included contractual protections, such as service level agreements (SLAs) that guard against shortfalls in performance or disruption. Additionally, defining quick and effective communications protocols between the organization and the third-party co-manufacturer will allow for timely identification of key issues and bottlenecks and enable agility in handling these problems as they arise.

Q81 Where does a product recall procedure fit into a BCM program?

Every manufacturer should have a robust and tested product recall procedure as part of its standard operating procedures. The product recall process also should be integrated into the crisis management plan. An effective recall plan should include the following procedures:

- Pull product in the event an issue is discovered due to safety or quality concerns
- Communicate to customers and stakeholders about the issue
- Trace and isolate the product defect’s root cause
- Track mechanisms to determine defective product marketplace proliferation and elimination
- Dispose of the product in a financially and environmentally responsible manner.

Many industries are regulated to develop and test these plans. For a manufacturer, a product recall is among the most significant and potentially devastating crises that can occur, because it can affect not only finances and operations but also brand and reputation and people’s health and safety. Product recalls should be managed no differently from than any other significant crisis event. An interdisciplinary team of business-unit and corporate senior managers should consider all facets of managing the crisis.

In light of recent events, manufacturers must critically analyze their organizations to ensure risks threatening business continuity are appropriately mitigated, including for those events that were considered “black swans.”
Q82 Are there any special or unique considerations for government organizations with regard to business continuity planning?

For the most part, no — although circumstances may differ in specific countries. In the United States, most government agencies have adopted business continuity planning as part of contingency planning for their overall risk management program. At the U.S. federal government level, most agencies adhere to guidance set forth in the NIST/U.S. Chamber of Commerce paper, “Contingency Planning Guide for Federal Information Systems.”

Of note, some government agencies are moving beyond business continuity planning for many of their systems. They are planning for pandemics and other catastrophic events that not only may bring down data centers, but also eliminate command and control. This is referred to as devolution planning.

Q83 What are some common challenges or gaps that government organizations may need to consider as part of their business continuity planning?

Among the common gaps, government agencies may not perform sufficient testing and exercises to validate recovery strategies and procedures. Escalation and decision making often operate differently during an actual event versus what is articulated in plans. A strong testing program is critical to test crisis management and decision-making teams and leaders in different scenarios. Also, continuity planning processes often fail to cover all critical services — instead, they focus on those for which it is easier to demonstrate continuity (e.g., cloud-based systems). Government agencies should consider ways to enhance continuity planning to ensure that all critical business processes are covered by their continuity operations.

Another common business continuity planning challenge in government is siloes, with individual departments in an agency having their own plans that are unknown to other departments. Specifically, there can be challenges with linkages (or lack of effective linkage) to other internal plans and processes, such as incident management frameworks and information communications and technology (ICT) disaster recovery arrangements to support business critical functions. In addition, an agency’s role in the overall government response to an emergency will impact the agency’s specific internal business continuity risk management and planning. Across a government agency, there should be a central repository of business continuity plans that management can access immediately in the event of an emergency.

Finally, rotating personnel remains a challenge in government. Individuals designated to be responsible for updating and maintaining government agency business continuity plans will change jobs, and new personnel are not trained to carry out all of their responsibilities regarding continuity planning. This results in less effective preparation for a business interruption or catastrophic event.

Q84 What actions can government organizations take to remedy these gaps?

Government entities have compiled a number of leading practices in business continuity, including guidelines on training business continuity teams, testing, and exercises to evaluate recovery strategies and ensure the availability government information systems in the event of a catastrophe. Among the benefits of focusing more on business continuity training, testing and exercises include reinforcing the ability to conduct repeatable procedures, coordinating organizational communications, uncovering weaknesses in procedures, and identifying resource gaps.

Conducting these activities also can happen without adversely impacting government entities. They will help build confidence in the overall operations and maintenance of the government information system, increase the overall strength of the preparedness program, and improve the ability of team members to perform their roles and carry out their responsibilities regardless of adverse circumstances.

<td>Sarbanes-Oxley Act (SOX)</td>
<td>The Sarbanes-Oxley Act is a series of legislation established in 2002. From a compliance perspective, the most important sections within these are often considered to be 302, 401, 404, 409, 802 and 906. SOX controls regarding IT disaster recovery focus on backup and recovery requirements for all in-scope SOX applications and underlying data.</td>

</tbody>
</table>
| Tabletop Exercise            | A facilitated session with various recovery team members, with a conceptual walk-through of planning materials using test scenarios and a series of predeveloped test scripts for any combination of crisis management, business resumption and IT disaster recovery personnel. | • Easy to coordinate and execute  
• Low cost and relatively low effort required from participants  
• Identifies glaring gaps in plans  
• Safe place for discussion | • Lower value because of limited time and use of verbal discussion only  
• Requires use of many assumptions that may or may not hold true in a real disaster event |
| Simulation                   | Simulation of a disaster event to determine how well the plan responds to the specific event in the operational environment.                                                                                           | • Highest likelihood of identifying gaps in capabilities and the plan (both large and small) | • One of the costlier testing methods and the most impactful to the business if not isolated properly (i.e., could create unintended impact to the business if simulation efforts are unsuccessful) |
| Procedure Verification Test  | Evaluation of the logic of a specific procedure in determining if a deficiency exists through a combination of desk checks and simulations. Limited in scope to a specific process or business unit. | • Allows for a very focused, deep dive of an area, process or technology to identify a plan and/or configuration flaws | • Narrow in scope and related results                                                                                                                 |
| (Business Function Testing)  |                                                                                                                                                                                                                      |                                                                                                 |                                                                                             |
|                             |                                                                                                                                                                                                                      |                                                                                                 |                                                                                             |
|                             |                                                                                                                                                                                                                      |                                                                                                 |                                                                                             |
| Communication Testing        | Testing the accuracy and completeness of the organization’s employee call tree, customer contact information channels and critical supplier, vendor and business partner contact information. Testing can be done as part of a tabletop exercise or simulation or potentially as a standalone activity. This is a key component of the BCM process. | • Various modes of communication can be assessed (e.g., BCM alert system, email, text message, phone call, recorded message line)  
• Identifies gaps in coverage for employee and other internal stakeholders | • This testing type often ignores communications with critical third-party vendors, suppliers, regulators and law enforcement |
|                             |                                                                                                                                                                                                                      |                                                                                                 |                                                                                             |
|                             |                                                                                                                                                                                                                      |                                                                                                 |                                                                                             |
| IT Disaster Recovery Testing | An exercise to conduct an announced or unannounced disaster simulation and execute documented system recovery procedures. The primary objective is to verify that critical systems and backup data can be recovered based on a specific timeline and documented application, data and infrastructure interdependencies. | • Can be used to exercise “active-active” and “active-passive” IT continuity models | • Often focuses on specific systems or technologies and utilizes scenarios in isolation (e.g., SAN environment outage, VPN concentrator failure).  
• Failures of IT infrastructure often do not occur in silos during a true disaster event |
<table>
<thead>
<tr>
<th>Testing Type</th>
<th>Description/Attributes</th>
<th>Pros</th>
<th>Cons</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alternate Site Testing</td>
<td>A test of all restoration/recovery components at an alternate site. This should include a test of the organization’s ability to relocate staff to the alternate site, as well as a validation that recovery processes and IT assets operate.</td>
<td>• Validates if an alternate site is equipped to support failover recovery needs and helps organizations extrapolate how long they could persist in the alternate environment</td>
<td>• Capacity needs, requirements and timing may be hard to replicate in a test, as most companies will choose to perform this testing during the best possible time (versus the worst)</td>
</tr>
<tr>
<td>End-to-End Testing</td>
<td>A test of all aspects of alternate facilities, business processes and IT. An end-to-end test differs from an alternate site test in that critical suppliers/business partners and customers — internal or external — are included within the scope.</td>
<td>• This test typically validates connectivity to the business’s production site and examines all integration between internal and external stakeholders</td>
<td>• Very challenging, costly and time consuming to coordinate</td>
</tr>
<tr>
<td>Work From Home</td>
<td>Enabling employees to work from home or from a remote location when unable to work from a primary location. As the COVID-19 pandemic of 2020 has shown, having all employees working from home is a real possibility.</td>
<td>• Allows for continued productivity even when employee groups need to be dispersed</td>
<td>• Increased cost and strain on IT infrastructure supporting remote connectivity</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Helps to minimize spread of infectious diseases between employees</td>
<td>• Reduction in team communication and camaraderie unless compensated with technology (e.g., video conference calls)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Identifies what jobs can effectively be performed from outside of the office for a prolonged period</td>
<td></td>
</tr>
<tr>
<td>Pandemic Simulation</td>
<td>A testing scenario focused on the potential disruptions caused by a pandemic and its potential effects on the business (e.g., losing a large portion of the workforce due to illness at the same time).</td>
<td>• Identifies areas where resources are thin and require cross-training</td>
<td>• Various characteristics about the pandemic (e.g., how long it lasts, length of illness, transmission rate) must all be assumed for the simulation, however, all these things are very hard to predict with real pandemics</td>
</tr>
<tr>
<td>Crisis Management Simulation</td>
<td>A testing option focused on convening only the crisis management team to drill on how various types of situations would be handled and the types of decisions that would need to be made, by whom and on what timeline. Often leverages the “tabletop” approach.</td>
<td>• Frequent exercises like this drive the level of communication and cohesion of the crisis management team</td>
<td>• Requires many assumptions to be made regarding how things would work “in real life”</td>
</tr>

</table>
Protiviti (www.protiviti.com) is a global consulting firm that delivers deep expertise, objective insights, a tailored approach and unparalleled collaboration to help leaders confidently face the future. Protiviti and our independent and locally owned Member Firms provide clients with consulting and managed solutions in finance, technology, operations, data, analytics, governance, risk and internal audit through our network of more than 85 offices in over 25 countries.

Named to the 2020 Fortune 100 Best Companies to Work For® list, Protiviti has served more than 60 percent of Fortune 1000 and 35 percent of Fortune Global 500 companies. The firm also works with smaller, growing companies, including those looking to go public, as well as with government agencies. Protiviti is a wholly owned subsidiary of Robert Half (NYSE: RHI). Founded in 1948, Robert Half is a member of the S&P 500 index.

ABOUT OUR BUSINESS CONTINUITY MANAGEMENT

Protiviti’s business continuity and resilience experts help CTOs, CIOs, CISOs, CROs, CFOs and other executive leadership assess, implement and maintain all aspects of business continuity management (BCM) into a cohesive set of integrated and repeatable processes.

Our BCM professionals employ a proven methodology that focuses on ensuring the expedient response, recovery and restoration of critical business processes due to unplanned business interruptions. Our approach is business-oriented and based on risks related to an organization’s key business process drivers. We concentrate on operational risk via the evaluation of processes and all interdependent people, infrastructure, information and facilities that are essential to an organization’s critical business processes.

Some companies have a greater risk tolerance than others; therefore, implementation efforts may range from a tailored scope to a full-scale business continuity program. It is our objective to provide you with the necessary information, based on leading practices, to make the best decisions for your organization. We will provide an assessment of the risks you face and present tailored options for risk mitigation. This enables you to make the most informed decisions regarding business continuity management within your organization.
